1 The pMath Computer Algebra System Library

Author:

Peter Frentrup

Date:

2008

Introduction

pMath is a free CAS for Windows and Unix like systems. The whole CAS consists of two independant projects:

- The pMath library documented here, which implements the parser, interpreter, mathematical functionality and OS binding.
- The Richmath library for a graphical front-end.

You as a user (front-end or module programmer) of the pMath library just have to `#include <pmath.h>` and link with the appropriate library file.

Links/Dependencies

pMath is build on top of several open source libraries:

- GMP (<http://gmplib.org>)
- MPFR (<http://www.mpfr.org>)
- iconv (e.g. <http://www.gnu.org/software/libiconv>)
- PCRE (<http://www.pcre.org>)

2 Todo List

Class `pmath_thread_t` Implement `pmath_run_parallel(number_of_parallel_threads, callback)`.

Group `cpp_binding` Document the Expr helper functions.

Global `pmath_thread_send_wait` Check, what happens if mq belongs to a parent thread.

3 Deprecated List

Global `pmath_symbol_t::pmath_symbol_get_value(pmath_symbol_t symbol)`

Global `pmath_symbol_t::pmath_symbol_set_value(pmath_symbol_t symbol, pmath_t value)`

Global `pmath_symbol_t::pmath_symbol_synchronized(pmath_symbol_t symbol, pmath_callback_t callback, void *data)`

4 Module Index

4.1 Modules

Here is a list of all modules:

Front-ends	91

5 Data Structure Index

5.1 Class Hierarchy

This inheritance list is sorted roughly, but not completely, alphabetically:

pmath::Expr	93
pmath::String	113
pmath::Gather	95
pmath_binary_file_api_t	96
pmath_cstr_writer_info_t	96
pmath_span_array_t	103
pmath_span_t	105
pmath_stack_t	105
pmath_t	109
pmath_custom_t	97
pmath_messages_t	101
pmath_expr_t	97

<code>pmath_number_t</code>	102
<code>pmath_float_t</code>	99
<code>pmath_rational_t</code>	103
<code>pmath_integer_t</code>	100
<code>pmath_quotient_t</code>	102
<code>pmath_string_t</code>	105
<code>pmath_symbol_t</code>	107
<code>pmath_text_file_api_t</code>	110
<code>pmath_thread_t</code>	111
<code>pmath_threadlock_t</code>	113

6 Data Structure Index

6.1 Data Structures

Here are the data structures with brief descriptions:

<code>pmath::Expr</code> (A wrapper for <code>pmath_t</code> and derived types)	93
<code>pmath::Gather</code> (Utility class for emitting and gathering expressions/building lists Gathering begins with the construction of the object and ends with a call to <code>end()</code> or the object destruction)	95
<code>pmath_binary_file_api_t</code> (Access functions for binary files)	96
<code>pmath_cstr_writer_info_t</code> (Additional information for <code>pmath_utf8_writer()</code> or <code>pmath_native_writer()</code>)	96
<code>pmath_custom_t</code> (The Custom Object class)	97
<code>pmath_expr_t</code> (The Expression class)	97
<code>pmath_float_t</code> (The Floating Point Number class)	99
<code>pmath_integer_t</code> (The Integer class)	100
<code>pmath_messages_t</code> (A message queue for interthread communication)	101
<code>pmath_number_t</code> (The abstract Number class)	102
<code>pmath_quotient_t</code> (The Quotient class)	102
<code>pmath_rational_t</code> (The abstract Rational Number class)	103
<code>pmath_span_array_t</code> (Internal flat representaion of spans)	103

pmath_span_t (Represents a span in a span-array)	105
pmath_stack_t (The type of pMath's threadsafe stacks)	105
pmath_string_t (The string class)	105
pmath_symbol_t (The Symbol class)	107
pmath_t (The basic type of all pMath objects)	109
pmath_text_file_api_t (Access functions for text files)	110
pmath_thread_t (The Representation of a thread)	111
pmath_threadlock_t (A reentrant lock for threads)	113
pmath::String (A wrapper for pmath_string_t)	113

7 Module Documentation

7.1 Custom Objects

Encapsulate arbitrary data in pMath objects.

Data Structures

- class [pmath_custom_t](#)
The Custom Object class.

Functions

- PMATH_API [pmath_custom_t](#) [pmath_custom_t::pmath_custom_new](#) (void *data, [pmath_callback_t](#) destructor)
Create a custom object.
- PMATH_API void * [pmath_custom_t::pmath_custom_get_data](#) ([pmath_custom_t](#) custom)
Get a custom object's data member.
- PMATH_API [pmath_bool_t](#) [pmath_custom_t::pmath_custom_has_destructor](#) ([pmath_custom_t](#) custom, [pmath_callback_t](#) dtor)
Get a custom object's data destructor.

7.1.1 Detailed Description

Encapsulate arbitrary data in pMath objects.

Custom Objects consist of a pointer and a destructor. The destructor is called (with the pointer as its argument) when the custom object's reference pointer yields zero.

Custom Objects are not evaluateable. This means evaluation of such an object returns NULL. But you can store custom objects in symbols (directly with `pmath_symbol_set_value()`).

A symbol that holds a custom object remains unevaluated. It can also contain function definitions. But those must be set *after* setting the value with `pmath_symbol_set_value(my_symbol, my_custom_object)`:

Example: You want to store a custom object and a function definition in a symbol (`my_symbol/:` `answer(my_symbol):= 42`).

```
pmath_custom_t my_custom_object = pmath_custom_new(my_data, my_destructor);
pmath_symbol_set_value(my_symbol, my_custom_object);

pmath_unref(pmath_evaluate(
    pmath_parse_string("'1'/: answer('1'):= 42", 1, pmath_ref(my_symbol))));
```

7.1.2 Function Documentation

7.1.2.1 PMATH_API `pmath_custom_t pmath_custom_new (void * data, pmath_callback_t destructor)` [inherited]

Create a custom object.

Parameters:

data An arbitrary pointer.

destructor A function that will be called on object destruction to enable freeing of *data*.

Returns:

A custom object or NULL on failure (in that case, *destructor(data)* is called immediately).

7.1.2.2 PMATH_API `void * pmath_custom_get_data (pmath_custom_t custom)` [inherited]

Get a custom object's data member.

Parameters:

custom A custom object.

Returns:

The objects data member or NULL if *custom* is NULL.

Note that you cannot assume anything about the content of this pointer unless you know its destructor (check `pmath_custom_has_destructor`).

All access to **data* must be threadsafe/synchronized. By convention, you are the only one who moves custom objects with your destructor around (other modules should not handle custom objects, whose destructor they do not know). And normally, each of your custom objects are stored in one symbols. So synchronization can be done with `pmath_symbol_synchronized()`. If one of these conditions is not met and a custom object could be accessed from multiple threads ([Multithreading with pMath](#)), you must also store a synchronization object (e.g. symbol or threadlock) in the *data* member und use this.

7.1.2.3 PMATH_API `pmath_bool_t` `pmath_custom_has_destructor` (`pmath_custom_t` *custom*, `pmath_callback_t` *dtor*) [inherited]

Get a custom object's data destructor.

Parameters:

custom A custom object.

dtor A callback function.

Returns:

TRUE if the object's destructor is *dtor*.

7.2 Expressions

Expression objects in pMath.

Data Structures

- class `pmath_expr_t`
The Expression class.

Functions

- PMATH_API `pmath_expr_t` `pmath_expr_t::pmath_expr_new` (`pmath_t` head, `size_t` length)
Create a new expression.
- PMATH_API `pmath_expr_t` `pmath_expr_t::pmath_expr_new_extended` (`pmath_t` head, `size_t` length,...)
Create a new expression with all items given.
- PMATH_API `pmath_expr_t` `pmath_expr_t::pmath_expr_resize` (`pmath_expr_t` expr, `size_t` new_length)
Resize an expression.
- PMATH_API `pmath_expr_t` `pmath_expr_t::pmath_expr_append` (`pmath_expr_t` expr, `size_t` count,...)
Append some items to an expression.
- PMATH_API `size_t` `pmath_expr_t::pmath_expr_length` (`pmath_expr_t` expr)
Get an expression's length.
- PMATH_API `pmath_t` `pmath_expr_t::pmath_expr_get_item` (`pmath_expr_t` expr, `size_t` index)
Get an item from an expression.
- PMATH_API `pmath_expr_t` `pmath_expr_t::pmath_expr_get_item_range` (`pmath_expr_t` expr, `size_t` start, `size_t` length)

Get multiple items from an expression.

- PMATH_API [pmath_expr_t](#) [pmath_expr_t::pmath_expr_set_item](#) ([pmath_expr_t](#) expr, [size_t](#) index, [pmath_t](#) item)

Set an item in an expression.

- PMATH_API [pmath_expr_t](#) [pmath_expr_t::pmath_expr_remove_all](#) ([pmath_expr_t](#) expr, [pmath_t](#) rem)

Remove all occurrences of an object from an expression.

- PMATH_API [pmath_expr_t](#) [pmath_expr_t::pmath_expr_sort](#) ([pmath_expr_t](#) expr)

Sort an expression.

- PMATH_API [pmath_expr_t](#) [pmath_expr_t::pmath_expr_flatten](#) ([pmath_expr_t](#) expr, [pmath_t](#) head, [size_t](#) depth)

Flatten an expression.

7.2.1 Detailed Description

Expression objects in pMath.

Any pMath language-level expression (lists, terms, function calls, ...) is stored in a [pmath_expr_t](#) – an array of pMath objects.

See also:

[Object Utility Functions](#)

7.2.2 Function Documentation

7.2.2.1 PMATH_API [pmath_expr_t](#) [pmath_expr_new](#) ([pmath_t](#) head, [size_t](#) length) [inherited]

Create a new expression.

Parameters:

head The expression's head (index 0). Do not use them after the call.

length The number of additional items in the expression.

Returns:

NULL or a new expression with head at index 0 and all other items initialized to NULL. You must destroy it with [pmath_unref\(\)](#).

7.2.2.2 PMATH_API [pmath_expr_t](#) [pmath_expr_new_extended](#) ([pmath_t](#) head, [size_t](#) length, ...) [inherited]

Create a new expression with all items given.

Parameters:

head The expression's head (index 0). Do not use them after the call.

length The number of additional items in the expression.

... exactly length pmath_ts. Do not use them after the call.

Returns:

NULL or a new expression with head at index 0 all items at index $i = 1..length$ initialized to the i 'th argument in '...'. You must destroy it with [pmath_unref\(\)](#).

7.2.2.3 PMATH_API pmath_expr_t pmath_expr_resize (pmath_expr_t *expr*, size_t *new_length*) [inherited]

Resize an expression.

Parameters:

expr The old expression. It will be freed/invalid after the call.

new_length The new length of the expression.

Returns:

NULL or a new expression of length new_length. You must destroy it with [pmath_unref\(\)](#).

If *expr*'s length is less than or equals to new_length, all items at $1..(expr's\ length)$ are be copied and the rest is initialized with NULL. Otherwise, all items at $1..new_length$ are copied, those at $(new_length+1)..(expr's\ length)$ are be freed and the rest is initialized with NULL.

7.2.2.4 PMATH_API pmath_expr_t pmath_expr_append (pmath_expr_t *expr*, size_t *count*, ...) [inherited]

Append some items to an expression.

Parameters:

expr The old expression. It will be freed/invalid after the call.

count The number of items to append.

... exactly count pmath_ts. Do not use them after the call.

Returns:

NULL or a new expression that contains all items of *expr* followed by the items in '...'. You must destroy it with [pmath_unref\(\)](#).

If *expr* == NULL, the returns value is `pmath_expr_new_extended(NULL,count,...)`.

7.2.2.5 PMATH_API size_t pmath_expr_length (pmath_expr_t *expr*) [inherited]

Get an expression's length.

Parameters:

expr A pMath expression.

Returns:

The number of items in *expr* (not counting the head).

7.2.2.6 PMATH_API pmath_t pmath_expr_get_item (pmath_expr_t *expr*, size_t *index*) [inherited]

Get an item from an expression.

Parameters:

expr A pMath expression.

index The index of the item.

Returns:

A copy of the requested item, if *index* is not greater than the length of *expr* and NULL otherwise. You must destroy it with [pmath_unref\(\)](#).

7.2.2.7 PMATH_API pmath_expr_t pmath_expr_get_item_range (pmath_expr_t *expr*, size_t *start*, size_t *length*) [inherited]

Get multiple items from an expression.

Parameters:

expr A pMath expression. It will **not** be destroyed.

start The start index of the items.

length The number of the items.

Returns:

A new expression with the same head as *expr*. Its length is $\max(0, \min(\text{start} + \text{length}, 1 + \text{pmath_expr_length}(\text{expr})) - \text{start})$ and it contains the items from *expr* beginning at index *start*.

7.2.2.8 PMATH_API `pmath_expr_t` `pmath_expr_set_item` (`pmath_expr_t` *expr*, `size_t` *index*, `pmath_t` *item*) [inherited]

Set an item in an expression.

Parameters:

expr A pMath expression. It will be destroyed, do not use it after the call.

index The index of the to-be-changed item.

item The new value of the item. It will be destroyed, do not use it after the call.

Returns:

NULL or a new expression with item at index. You must destroy it with `pmath_unref()`.

If index is greater than *expr*'s length, item will be destroyed and the return value is *expr*.

7.2.2.9 PMATH_API `pmath_expr_t` `pmath_expr_remove_all` (`pmath_expr_t` *expr*, `pmath_t` *rem*) [inherited]

Remove all occurrences of an object from an expression.

Parameters:

expr A pMath expression. It will be destroyed, do not use it after the call.

rem The object to be removed. It will *not* be destroyed.

Returns:

NULL or a new expression that contains no occurrences of *rem* (except maybe the head). It is a shrunk version of *expr*.

7.2.2.10 PMATH_API `pmath_expr_t` `pmath_expr_sort` (`pmath_expr_t` *expr*) [inherited]

Sort an expression.

Parameters:

expr A pMath expression. It will be destroyed, do not use it after the call.

Returns:

A new expression where all items from *expr* are sorted (except the head, which remains unchanged).

7.2.2.11 PMATH_API `pmath_expr_t` `pmath_expr_flatten` (`pmath_expr_t` *expr*, `pmath_t` *head*, `size_t` *depth*) [*inherited*]

Flatten an expression.

Parameters:

- expr* A pMath expression. It will be destroyed, do not use it after the call.
- head* The head of items, that should be flattened out. It will be destroyed, so you can use ‘`pmath_expr_get_item(expr)`’ directly to use *expr*’s head.
- depth* The depth to which level flattening should be done. A value of 0 means ‘no flattening’.

Returns:

A new expression where all items, that have the same head as *expr*, will be flattened.

7.3 Numbers

Number objects in pMath.

Data Structures

- class `pmath_number_t`
The abstract Number class.
- class `pmath_rational_t`
The abstract Rational Number class.
- class `pmath_integer_t`
The Integer class.
- class `pmath_quotient_t`
The Quotient class.
- class `pmath_float_t`
The Floating Point Number class.

Functions

- PMATH_API double `pmath_accuracy` (`pmath_t` *obj*)
Get the accuracy (in bits) of an object.
- PMATH_API double `pmath_precision` (`pmath_t` *obj*)
Get the precision (in bits) of an object.
- PMATH_API `pmath_t` `pmath_set_accuracy` (`pmath_t` *obj*, double *acc*)
Set an object’s accuracy in bits.

- PMATH_API `pmath_t pmath_set_precision` (`pmath_t` obj, double prec)
Set an object's accuracy in bits.
- PMATH_API `pmath_t pmath_approximate` (`pmath_t` obj, double prec, double acc)
Approximate an object.
- PMATH_API `pmath_integer_t pmath_integer_t::pmath_integer_new_si` (signed long int si)
Create an integer object from a signed long.
- PMATH_API `pmath_integer_t pmath_integer_t::pmath_integer_new_ui` (unsigned long int ui)
Create an integer object from an unsigned long.
- PMATH_API `pmath_integer_t pmath_integer_t::pmath_integer_new_size` (`size_t` size)
Create an integer object from an size_t.
- PMATH_API `pmath_integer_t pmath_integer_t::pmath_integer_new_data` (`size_t` count, int order, int size, int endian, `size_t` nails, const void *data)
Create an integer object from a data buffer.
- PMATH_API `pmath_integer_t pmath_integer_t::pmath_integer_new_str` (const char *str, int base)
Create an integer object from a C String.
- PMATH_API `pmath_rational_t pmath_rational_t::pmath_rational_new` (`pmath_integer_t` numerator, `pmath_integer_t` denominator)
Create a rational number.
- PMATH_API `pmath_integer_t pmath_rational_t::pmath_rational_numerator` (`pmath_rational_t` rational)
Get the numerator of a rational number.
- PMATH_API `pmath_integer_t pmath_rational_t::pmath_rational_denominator` (`pmath_rational_t` rational)
Get the denominator of a rational number.
- PMATH_API `pmath_number_t pmath_float_t::pmath_float_new_str` (const char *str, int base, `pmath_precision_control_t` precision_control, double base_precision_accuracy)
Create a floating point number from a string.
- PMATH_API `pmath_float_t pmath_float_t::pmath_float_new_d` (double dbl)
Create a machine-precision floating point number from a double.
- PMATH_API `pmath_bool_t pmath_integer_t::pmath_integer_fits_si` (`pmath_integer_t` integer)
Find out whether a pMath integer fits into a signed long int.
- PMATH_API `pmath_bool_t pmath_integer_t::pmath_integer_fits_ui` (`pmath_integer_t` integer)
Find out whether a pMath integer fits into a unsigned long int.
- PMATH_API signed long int `pmath_integer_t::pmath_integer_get_si` (`pmath_integer_t` integer)
Convert a pMath integer to a signed long int.

- PMATH_API unsigned long int `pmath_integer_t::pmath_integer_get_ui` (`pmath_integer_t` integer)
Convert a pMath integer to a unsigned long int.
- PMATH_API double `pmath_number_t::pmath_number_get_d` (`pmath_number_t` number)
Convert a pMath number to a double.
- PMATH_API int `pmath_number_t::pmath_number_sign` (`pmath_number_t` num)
Get a number's sign.
- PMATH_API `pmath_number_t` `pmath_number_t::pmath_number_neg` (`pmath_number_t` num)
Get a number's negative.

7.3.1 Detailed Description

Number objects in pMath.

pMath uses The GNU Multiple Precision Library (<http://gmplib.org/>) for integer and rational arithmetic and The MPFR library (<http://www.mpfr.org/>) for floating point arithmetic.

7.3.2 Function Documentation

7.3.2.1 PMATH_API double `pmath_accuracy` (`pmath_t obj`)

Get the accuracy (in bits) of an object.

Parameters:

obj An object. It will be freed.

Returns:

The number of known bits after the decimal point.

HUGE_VAL is given for exact quantities. If *obj* is an expression, the minimum of its items' accuracies is returned.

Note that the builtin function Accuracy() uses base 10, but this function operates on base 2.

7.3.2.2 PMATH_API double `pmath_precision` (`pmath_t obj`)

Get the precision (in bits) of an object.

Parameters:

obj An object. It will be freed.

Returns:

The number of known bits.

HUGE_VAL is given for exact quantities. -HUGE_VAL means "machine precision". If *obj* is an expression, the minimum of its items' accuracies is returned.

Note that the builtin function Precision() uses base 10, but this function operates on base 2.

7.3.2.3 PMATH_API pmath_t pmath_set_accuracy (pmath_t *obj*, double *acc*)

Set an object's accuracy in bits.

Parameters:

obj An object. It will be freed.

acc The new number of known bits after the decimal point.

Returns:

The new object.

Use `acc == -HUGE_VAL` for machine precision.

Note that the builtin function SetAccuracy() uses base 10, but this function operates on base 2.

7.3.2.4 PMATH_API pmath_t pmath_set_precision (pmath_t *obj*, double *prec*)

Set an object's accuracy in bits.

Parameters:

obj An object. It will be freed.

prec The new number of known bits.

Returns:

The new object.

Use `prec == -HUGE_VAL` for machine precision.

Note that the builtin function SetPrecision() uses base 10, but this function operates on base 2.

7.3.2.5 PMATH_API pmath_t pmath_approximate (pmath_t *obj*, double *prec*, double *acc*)

Approximate an object.

Parameters:

obj An object. It will be freed.

prec The requested precision in bits.

acc The requested accuracy in bits.

Returns:

The approximated object.

Use `prec == -HUGE_VAL` or `acc == -HUGE_VAL` for machine precision. Use `acc == HUGE_VAL` if the accuracy is not important and use `prec == HUGE_VAL` if the precision is not important.

7.3.2.6 PMATH_API pmath_integer_t pmath_integer_new_si (signed long int *si*) [inherited]

Create an integer object from a signed long.

Parameters:

si A signed long int.

Returns:

A pMath integer with the specified value or NULL.

7.3.2.7 PMATH_API pmath_integer_t pmath_integer_new_ui (unsigned long int *ui*) [inherited]

Create an integer object from an unsigned long.

Parameters:

ui An unsigned long int.

Returns:

A pMath integer with the specified value or NULL.

7.3.2.8 PMATH_API pmath_integer_t pmath_integer_new_size (size_t *size*) [inherited]

Create an integer object from an size_t.

Parameters:

size A size_t value.

Returns:

A pMath integer with the specified value or NULL.

Note that on Win64, `sizeof(long) == 4`, but `sizeof(size_t) == 8`.

7.3.2.9 PMATH_API `pmath_integer_t pmath_integer_new_data (size_t count, int order, int size, int endian, size_t nails, const void * data)` [inherited]

Create an integer object from a data buffer.

Parameters:

count The number of words to be read.

order The order of the words: 1 for most significant word first or -1 for least significant first.

size The size (in bytes) of a word.

endian The byte order within each word: 1 for most significant byte first, -1 for least significant first, or 0 for the native endianness of the CPU.

nails The most significant *nails* bits of each word are skipped. This can be 0 to use the full words.

data The buffer to read from.

Returns:

A non-negative integer.

See also:

GMP's `mpz_import()`

7.3.2.10 PMATH_API `pmath_integer_t pmath_integer_new_str (const char * str, int base)` [inherited]

Create an integer object from a C String.

Parameters:

str A string representing the value in base *base*.

base The base.

Returns:

A pMath integer with the specified value or NULL.

See GMP's `mpz_set_str` for mor information about the parameters.

7.3.2.11 PMATH_API `pmath_rational_t pmath_rational_new (pmath_integer_t numerator, pmath_integer_t denominator)` [inherited]

Create a rational number.

Parameters:

numerator The quotient's numerator. It will be freed.

denominator The quotient's denominator. It will be freed.

Returns:

An integer, if *denominator* divides *numerator* or a quotient in canonical form otherwise. If denominator is zero, NULL will be returned.

7.3.2.12 PMATH_API pmath_integer_t pmath_rational_numerator (pmath_rational_t *rational*)
[inherited]

Get the numerator of a rational number.

Parameters:

rational A rational number (integer or quotient). It wont be freed.

Returns:

A reference to the numerator of *rational* if it is a quotient or *rational* itself if it is an integer. You have to destroy the result e.g. with [pmath_unref\(\)](#).

7.3.2.13 PMATH_API pmath_integer_t pmath_rational_denominator (pmath_rational_t *rational*)
[inherited]

Get the denominator of a rational number.

Parameters:

rational A rational number (integer or quotient). It wont be freed.

Returns:

A reference to the denominator of *rational* if it is a quotient or 1 if it is an integer. You have to destroy the result e.g. with [pmath_unref\(\)](#).

7.3.2.14 PMATH_API pmath_number_t pmath_float_new_str (const char * *str*, int *base*, pmath_precision_control_t *precision_control*, double *base_precision_accuracy*)
[inherited]

Create a floating point number from a string.

Parameters:

str A C-string representing the value in a given *base*. It should have the form "ddd.ddd" or simply "ddd". An exponent can be appended with "ennn" or if *base* != 10 "@nnn".

base The base between 2 and 36.

precision_control flag for controlling the precision.

base_precision_accuracy given precision or accuracy, depending on the value of the above flag.

Returns:

a new pMath floating point number or NULL on error or the integer 0 (see below when this happens).

Remarks:

precision_control may have one of the following values:

- **PMATH_PREC_CTRL_AUTO:**
The precision is specified by the number of digits given in str. It may result in a pMath machine float, multi-precision float or integer.
The value of *base_precision_accuracy* will be ignored.
- **PMATH_PREC_CTRL_MACHINE_PREC:**
The result is a pMath machine float.
The value of *base_precision_accuracy* will be ignored.
- **PMATH_PREC_CTRL_GIVEN_PREC:**
If the number's value is 0, the integer 0 will be returned.
The precision is given by *base_precision_accuracy* (interpreted in the given base).
- **PMATH_PREC_CTRL_GIVEN_ACC:**
base_precision_accuracy specifies the accuracy (the number of known *base* -digits after the point). The precision is calculated appropriately.

For a multiprecision float $x \neq 0$ with absolute error dx , accuracy and precision are:

```
accuracy = -Log(base, dx)
precision = -Log(base, dx / Abs(x))
```

So $\text{precision} = \text{accuracy} + \text{Log}(\text{base}, \text{Abs}(x))$.

7.3.2.15 PMATH_API pmath_float_t pmath_float_new_d (double *dbl*) [inherited]

Create a machine-precision floating point number from a double.

Parameters:

dbl A double value.

Returns:

A pMath floating point number with the specified value or NULL.

7.3.2.16 PMATH_API pmath_bool_t pmath_integer_fits_si (pmath_integer_t *integer*) [inherited]

Find out whether a pMath integer fits into a signed long int.

Parameters:

integer A pMath integer. It wont be freed.

Returns:

TRUE iff the value is small enough for a signed long int.

7.3.2.17 PMATH_API pmath_bool_t pmath_integer_fits_ui (pmath_integer_t integer)
[inherited]

Find out whether a pMath integer fits into a unsigned long int.

Parameters:

integer A pMath integer. It wont be freed.

Returns:

TRUE iff the value is small enough for a unsigned long int.

7.3.2.18 PMATH_API signed long int pmath_integer_get_si (pmath_integer_t integer)
[inherited]

Convert a pMath integer to a signed long int.

Parameters:

integer A pMath integer. It wont be freed.

Returns:

The integer's value if it fits.

See also:

[pmath_integer_fits_si](#)

7.3.2.19 PMATH_API unsigned long int pmath_integer_get_ui (pmath_integer_t integer)
[inherited]

Convert a pMath integer to a unsigned long int.

Parameters:

integer A pMath integer. It wont be freed.

Returns:

The integer's value if it fits.

See also:

[pmath_integer_fits_ui](#)

7.3.2.20 PMATH_API double pmath_number_get_d (pmath_number_t *number*) [inherited]

Convert a pMath number to a double.

Parameters:

number A pMath number. It wont be freed.

Returns:

The number's value if it fits.

7.3.2.21 PMATH_API int pmath_number_sign (pmath_number_t *num*) [inherited]

Get a number's sign.

Parameters:

num A pMath number. It wont be freed.

Returns:

The number's sign (-1, 0 or 1)

7.3.2.22 PMATH_API pmath_number_t pmath_number_neg (pmath_number_t *num*) [inherited]

Get a number's negative.

Parameters:

num A pMath number. It will be freed, do not use it afterwards.

Returns:

-num

7.4 Objects - the Base of pMath

The basic class for all pMath objects.

Data Structures

- class `pmath_t`
The basic type of all pMath objects.

Defines

- `#define PMATH_IS_MAGIC(obj)`
Fast test, whether an object is a 'magic value'.
- `pmath_t::PMATH_IS_MAGIC(obj)`
Fast test, whether an object is a 'magic value'.

Typedefs

- `typedef int pmath_type_t`
The type or class of a pMath object.
- `typedef int pmath_write_options_t`
Options for `pmath_write()`.
- `typedef void(* pmath_proc_t)(pmath_t)`
A simple procedure operating on an object.
- `typedef void(* pmath_param_proc_t)(void *, pmath_t)`
A parameterized procedure operating on an object.
- `typedef pmath_t(* pmath_func_t)(pmath_t)`
A simple function operating on an object and returning one.
- `typedef unsigned int(* pmath_hash_func_t)(pmath_t)`
A hash function for an object.
- `typedef pmath_bool_t(* pmath_equal_func_t)(pmath_t, pmath_t)`
A comparison function for two objects.
- `typedef int(* pmath_compare_func_t)(pmath_t, pmath_t)`
A comparison function to determine the order of two objects.

Functions

- `PMATH_API unsigned int pmath_t::pmath_hash (pmath_t obj)`
Calculates an object's hash value.
- `PMATH_API pmath_bool_t pmath_t::pmath_equals (pmath_t objA, pmath_t objB)`
Compares two objects for identity.

- PMATH_API int [pmath_t::pmath_compare](#) ([pmath_t](#) objA, [pmath_t](#) objB)
Compares two objects syntactically.
- PMATH_API void [pmath_t::pmath_write](#) ([pmath_t](#) obj, [pmath_write_options_t](#) options, [pmath_write_func_t](#) write, void *user)
Write an object to a stream.
- PMATH_API [pmath_bool_t](#) [pmath_t::pmath_is_evaluated](#) ([pmath_t](#) obj)
Test whether an object is already evaluated.

7.4.1 Detailed Description

The basic class for all pMath objects.

pMath works on objects. They can be expressions (trees of pMath objects), symbols, values, strings or ‘magic objects’ (integer value between 0 and 255).

See also:

[Object Utility Functions](#)

7.4.2 Define Documentation

7.4.2.1 #define PMATH_IS_MAGIC(obj)

Fast test, whether an object is a ‘magic value’.

Parameters:

obj A pMath object

Returns:

A boolean value.

This is the faster equivalent to `pmath_instance_of(obj, PMATH_TYPE_MAGIC)`.

See also:

[pmath_instance_of\(\)](#)

7.4.2.2 PMATH_IS_MAGIC(obj) [inherited]

Fast test, whether an object is a ‘magic value’.

Parameters:

obj A pMath object

Returns:

A boolean value.

This is the faster equivalent to `pmath_instance_of(obj, PMATH_TYPE_MAGIC)`.

See also:

[pmath_instance_of\(\)](#)

7.4.3 Typedef Documentation**7.4.3.1 typedef int pmath_type_t**

The type or class of a pMath object.

This is a bitset of the `PMATH_TYPE_XXX` constants:

- `PMATH_TYPE_MAGIC` `PMATH_TYPE_MAGIC`: The object is a ‘magic number’, which is any integer value between 0 and 255 cast to ([pmath_t](#)). These values have special meanings:
 - `NULL` This is simply ‘nothing’. It is often used to indicate that there is not enough memory.
 - `PMATH_UNDEFINED` `PMATH_UNDEFINED` Symbol values are initialized with `PMATH_UNDEFINED`. This is done to enable saving the value `NULL` in a symbol.

Any function that returns or operates on a [pmath_t](#) may return `NULL`. Exceptions are allways explicitly stated in the documentation.

- `PMATH_TYPE_INTEGER`: The object is an integer value. You can cast it to [pmath_integer_t](#), [pmath_rational_t](#) and [pmath_number_t](#).
- `PMATH_TYPE_QUOTIENT`: The object is a reduced quotient of two integer values, where the denominator is never 0 or 1. Because of this, you almost never test for this type, but for `PMATH_TYPE_RATIONAL`, since the result of an operation on two quotients may be an integer. You can cast quotient objects to [pmath_rational_t](#) and thus to [pmath_number_t](#) too.
- `PMATH_TYPE_RATIONAL`: The object is either an integer or a quotient. You can cast it to [pmath_rational_t](#) and thus to [pmath_number_t](#) too.
- `PMATH_TYPE_MP_FLOAT`: The object is a floating point number with arbitrary precision. You can cast it to [pmath_float_t](#) and [pmath_number_t](#).
- `PMATH_TYPE_MACHINE_FLOAT`: The object is a floating point number with machine precision. You can cast it to [pmath_float_t](#) and [pmath_number_t](#).
- `PMATH_TYPE_FLOAT`: The object is either `PMATH_TYPE_MP_FLOAT` or `PMATH_TYPE_MACHINE_FLOAT`.
- `PMATH_TYPE_NUMBER`: The object is a numerical value (integer, quotient, floating point number). You can cast it to [pmath_number_t](#).

Note that complex numbers are stored as expressions and thus are not numbers in this sense. Additionally, algebraic and special constants as `Sqrt(2)` or `Pi` are not numbers, but symbols or expressions (e.g. `Sqrt(2)`).

- `PMATH_TYPE_STRING`: The object is a string. You can cast it to [`pmath_string_t`](#).
- `PMATH_TYPE_SYMBOL`: The object is a symbol. You can cast it to [`pmath_symbol_t`](#).
- `PMATH_TYPE_EXPRESSION`: The object is an expression. You can cast it to [`pmath_expr_t`](#).
- `PMATH_TYPE_CUSTOM`: The object is a custom object. You can cast it to [`pmath_custom_t`](#).
- `PMATH_TYPE_EVALUATABLE`: The object is evaluable. That means, if a symbol has this object as its value, the object will be returned. Function definition rules and custom objects are an example of non-evaluable objects.

7.4.3.2 `typedef int pmath_write_options_t`

Options for [`pmath_write\(\)`](#).

These options can be one or more of the following:

- `PMATH_WRITE_OPTIONS_FULLEXPR` All expressions are written in the form `f(a, b, ...)` without any syntactic sugar.

Supersedes `PMATH_WRITE_OPTIONS_INPUTEXPR`.

- `PMATH_WRITE_OPTIONS_FULLSTR` Strings are written with quotes and escape sequences.
- `PMATH_WRITE_OPTIONS_FULLNAME` Names are written with their full namespace path.
- `PMATH_WRITE_OPTIONS_INPUTEXPR` Expressions are written in a form that is valid pMath input.

Note that this does not automatically imply `PMATH_WRITE_OPTIONS_FULLSTR`.

7.4.3.3 `typedef void(* pmath_proc_t)(pmath_t)`

A simple procedure operating on an object.

It depends on the context whether the argument is destroyed by the procedure or not.

7.4.3.4 `typedef void(* pmath_param_proc_t)(void *, pmath_t)`

A parameterized procedure operating on an object.

It depends on the context whether the (second) argument is destroyed by the procedure or not.

7.4.3.5 typedef pmath_t(* pmath_func_t)(pmath_t)

A simple function operating on an object and returning one.

It depends on the context whether the argument is destroyed by the function or not.

7.4.3.6 typedef unsigned int(* pmath_hash_func_t)(pmath_t)

A hash function for an object.

If two objects equal, their hash values equal.

7.4.3.7 typedef pmath_bool_t(* pmath_equal_func_t)(pmath_t, pmath_t)

A comparison function for two objects.

The return value is nonzero, if both objects equal and zero otherwise. Note that a `pmath_compare_func_t` cannot be cast to `pmath_equal_func_t`, because their return values have opposite meanings.

7.4.3.8 typedef int(* pmath_compare_func_t)(pmath_t, pmath_t)

A comparison function to determine the order of two objects.

The return value is <0 , $=0$ or >0 , if the first argument is less, equal to or greater than the second respectively. Both arguments won't be destroyed by the function.

7.4.4 Function Documentation**7.4.4.1 PMATH_API unsigned int pmath_hash (pmath_t *obj*)** [inherited]

Calculates an object's hash value.

Parameters:

obj The object.

Returns:

A hash value.

`pmath_equals(A, B)` implies `pmath_hash(A) == pmath_hash(B)`.

7.4.4.2 PMATH_API pmath_bool_t pmath_equals (pmath_t *objA*, pmath_t *objB*)
[inherited]

Compares two objects for identity.

Parameters:

objA The first object.

objB The second one.

Returns:

TRUE iff both objects are identical.

‘identity’ means, that $X \neq Y$ is possible, even if X and Y evaluate to the same value.

If *objA* and *objB* are symbols, the result is identical to testing *objA* == *objB*.

Note:

`pmath_equals(A, B)` might return FALSE although `pmath_compare(A, B) == 0` e.g. for an integer A and q floating point value B.

7.4.4.3 PMATH_API int `pmath_compare` (`pmath_t objA`, `pmath_t objB`) [inherited]

Compares two objects syntactically.

Parameters:

objA The first object.

objB The second one.

Returns:

< 0 if *objA* is less than *objB*, == 0 if both are equal and > 0 if *objA* is greater than *objB*.

‘syntactically’ means that for two symbols X and Y, `pmath_compare(X, Y) < 0` even if X:=2 and Y:=1, because X appears before Y in the alphabet.

Note:

`pmath_equals(A, B)` might return FALSE although `pmath_compare(A, B) == 0` e.g. for an integer A and q floating point value B.

7.4.4.4 PMATH_API void `pmath_write` (`pmath_t obj`, `pmath_write_options_t options`, `pmath_write_func_t write`, `void * user`) [inherited]

Write an object to a stream.

Parameters:

obj The object to be written.

options Some options defining the format.

write The stream's output function.

user The user-argument of write (e.g. the stream itself).

See also:

[pmath_utf8_writer](#)

7.4.4.5 PMATH_API `pmath_bool_t pmath_is_evaluated (pmath_t obj)` [inherited]

Test whether an object is already evaluated.

Parameters:

obj Any pMath object. It will **not** be freed.

Returns:

TRUE if a call to `pmath_evaluate` would not change the object.

7.5 Strings

String objects in pMath.

Data Structures

- struct [pmath_cstr_writer_info_t](#)
Additional information for [pmath_utf8_writer\(\)](#) or [pmath_native_writer\(\)](#).
- class [pmath_string_t](#)
The string class.

Defines

- #define [PMATH_C_STRING](#)(cstr) `pmath_string_insert_latin1(NULL, 0, (cstr), -1)`
Short form to convert a C String to a pMath String.
- [pmath_string_t::PMATH_C_STRING](#)(cstr)
Short form to convert a C String to a pMath String.

Functions

- PMATH_API void [pmath_utf8_writer](#) (void *user, const uint16_t *data, int len)
A write function for [pmath_write\(\)](#) that converts to utf8.
- PMATH_API void [pmath_native_writer](#) (void *user, const uint16_t *data, int len)
A write function for [pmath_write\(\)](#) that converts to the current console encoding.

- PMATH_API uint32_t [pmath_char_from_name](#) (const char *name)
Get a named character.
- PMATH_API const char * [pmath_char_to_name](#) (uint32_t unichar)
Get a character's name.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_new](#) (int capacity)
Create an empty pMath String.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_insert_latin1](#) ([pmath_string_t](#) str, int inspos, const char *ins, int inslen)
Insert an Latin-1 encoded buffer into a pMath String.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_from_utf8](#) (const char *str, int len)
Convert an UTF-8 encoded buffer to a pMath String.
- PMATH_API char * [pmath_string_t::pmath_string_to_utf8](#) ([pmath_string_t](#) str, int *result_len)
Convert a pMath string to a zero-terminated UTF-8 string.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_from_native](#) (const char *str, int len)
Convert a string buffer in the current console character encoding to a pMath String.
- PMATH_API char * [pmath_string_t::pmath_string_to_native](#) ([pmath_string_t](#) str, int *result_len)
Convert a pMath string to a string in the current console character encoding.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_insert_codepage](#) ([pmath_string_t](#) str, int inspos, const char *ins, int inslen, const uint16_t *cp)
Insert a byte string into a pMath string using a translation array.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_insert_ucs2](#) ([pmath_string_t](#) str, int inspos, const uint16_t *ins, int inslen)
Insert a UCS-2 buffer into a pMath String.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_insert](#) ([pmath_string_t](#) str, int inspos, [pmath_string_t](#) ins)
Insert one pMath String into another pMath String.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_concat](#) ([pmath_string_t](#) prefix, [pmath_string_t](#) postfix)
Concatenate two pMath Strings.
- PMATH_API [pmath_string_t](#) [pmath_string_t::pmath_string_part](#) ([pmath_string_t](#) string, int start, int length)
Extract a substring of a pMath String.
- PMATH_API const uint16_t * [pmath_string_t::pmath_string_buffer](#) ([pmath_string_t](#) string)
Get a string's buffer for reading.
- PMATH_API int [pmath_string_t::pmath_string_length](#) ([pmath_string_t](#) string)

Get a string's length.

- PMATH_API `pmath_bool_t pmath_string_t::pmath_string_equals_latin1 (pmath_string_t string, const char *latin1)`

Compare a pMth sting with a C string.

7.5.1 Detailed Description

String objects in pMath.

pMath stores strings in UCS-2 format (like Java and Windows NT). But pMath strings are not zero terminated.

Do not confuse pMath String characters (`uint16_t`) with `wchar_t`: `sizeof(wchar_t)` differs on different Systems (Linux: 4 bytes, Windows: 2 bytes). So you cannot simply convert `wchar_t*` strings to pMath strings.

7.5.2 Define Documentation

7.5.2.1 `#define PMATH_C_STRING(cstr) pmath_string_insert_latin1(NULL, 0, (cstr), -1)`

Short form to convert a C String to a pMath String.

Parameters:

cstr A C String (zero-terminated char buffer).

Returns:

A pMath String representing the Latin-1 C string *cstr*.

This is a wrapper macro around `pmath_string_insert_latin1()`.

7.5.2.2 `PMATH_C_STRING(cstr)` [inherited]

Short form to convert a C String to a pMath String.

Parameters:

cstr A C String (zero-terminated char buffer).

Returns:

A pMath String representing the Latin-1 C string *cstr*.

This is a wrapper macro around `pmath_string_insert_latin1()`.

7.5.3 Function Documentation

7.5.3.1 PMATH_API void pmath_utf8_writer (void * *user*, const uint16_t * *data*, int *len*)

A *write* function for [pmath_write\(\)](#) that converts to utf8.

[pmath_write\(\)](#) writes output as utf16/ucs2. This function can be used to convert to utf8 on the fly. The *user* parameter to [pmath_write](#) must point to a [pmath_cstr_writer_info_t](#).

Here is an example on how to use it:

```
void my_utf8_output(FILE *f, const char *str){
    fprintf(f, "%s", str);
}

...

pmath_cstr_writer_info_t info;
info.write_cstr = (void(*) (void*, const char*))my_utf8_output;
info.user = stdout; // will be first argument of my_utf8_output

pmath_print(some_object, some_options, pmath_utf8_writer, &info);
```

7.5.3.2 PMATH_API void pmath_native_writer (void * *user*, const uint16_t * *data*, int *len*)

A *write* function for [pmath_write\(\)](#) that converts to the current console encoding.

This callback function is used like [pmath_utf8_writer\(\)](#).

7.5.3.3 PMATH_API uint32_t pmath_char_from_name (const char * *name*)

Get a named character.

Parameters:

name The ASCII-name of the character. e.g. "Sum"

Returns:

The character code or 0xFFFFFFFFU on error

7.5.3.4 PMATH_API const char* pmath_char_to_name (uint32_t *unichar*)

Get a character's name.

Parameters:

unichar A unicode character

Returns:

The ASCII-name or NULL if it is unnamed

7.5.3.5 PMATH_API pmath_string_t pmath_string_new (int *capacity*) [inherited]

Create an empty pMath String.

Parameters:

capacity The initial capacity of the string. Must not be negative.

Returns:

A new pMath String or NULL on failure. You must destroy it.

7.5.3.6 PMATH_API pmath_string_t pmath_string_insert_latin1 (pmath_string_t *str*, int *inspos*, const char * *ins*, int *inslen*) [inherited]

Insert an Latin-1 encoded buffer into a pMath String.

Parameters:

str A pMath String or NULL. It will be freed.

inspos The position, at which *ins* should be inserted in *str*.

ins A byte string.

inslen The length of *ins* or -1 if it is zero-terminated.

Returns:

NULL on failure or a pMath String. You must destroy it.

If *str* is NULL, it is assumed to be the empty string. The result is equivalent to a call to [pmath_string_insert_codepage\(\)](#) with a codepage that translates every byte *b* to (uint16_t)(unsigned char)b.

7.5.3.7 PMATH_API pmath_string_t pmath_string_from_utf8 (const char * *str*, int *len*) [inherited]

Convert an UTF-8 encoded buffer to a pMath String.

Parameters:

str A byte string. It wont be freed.

len The byte-length of *ins* or -1 if it is zero-terminated.

Returns:

NULL on failure or a pMath String. You must destroy it.

7.5.3.8 PMATH_API `char * pmath_string_to_utf8 (pmath_string_t str, int * result_len)` [inherited]

Convert a pMath string to a zero-terminated UTF-8 string.

Parameters:

str A pMath string. It wont be freed.

result_len Position, where the string length of the returned buffer may be stored.

Returns:

A zero-terminated UTF-8 string or NULL on error. You have to free the memory with `pmath_mem_free(result, *size_ptr)`.

Note:

pMath strings may contain embedded `”`, but C strings may not. However, the conversion is done to the whole string even though your C functions will only *see* the content up to the first `”`.

7.5.3.9 PMATH_API `pmath_string_t pmath_string_from_native (const char * str, int len)` [inherited]

Convert a string buffer in the current console character encoding to a pMath String.

Parameters:

str A byte string. It wont be freed.

len The byte-length of `ins` or -1 if it is zero-terminated.

Returns:

NULL on failure or a pMath String. You must destroy it.

7.5.3.10 PMATH_API `char * pmath_string_to_native (pmath_string_t str, int * result_len)` [inherited]

Convert a pMath string to a string in the current console character encoding.

Parameters:

str A pMath string. It wont be freed.

result_len Position, where the string length of the returned buffer may be stored.

Returns:

A zero terminated string or NULL on error. You have to free the memory with `pmath_mem_free(result, *size_ptr)`.

Note:

pMath strings may contain embedded `”`, but C strings may not. However, the conversion is done to the whole string even though your C functions will only *see* the content up to the first `”`.

7.5.3.11 PMATH_API pmath_string_t pmath_string_insert_codepage (pmath_string_t *str*, int *inspos*, const char * *ins*, int *inslen*, const uint16_t * *cp*) [inherited]

Insert a byte string into a pMath string using a translation array.

Parameters:

- str* A pMath String or NULL. It will be freed.
- inspos* The position, at which *ins* should be inserted in *str*.
- ins* A byte string.
- inslen* The length of *ins* or -1 if it is zero-terminated.
- cp* An array of 256 uint16_t values that are used to convert bytes to UCS-2 characters.

Returns:

NULL on failure or a pMath String. You must destroy it.

If *str* is NULL, it is assumed to be the empty string.

7.5.3.12 PMATH_API pmath_string_t pmath_string_insert_ucs2 (pmath_string_t *str*, int *inspos*, const uint16_t * *ins*, int *inslen*) [inherited]

Insert a UCS-2 buffer into a pMath String.

Parameters:

- str* A pMath String or NULL. It will be freed.
- inspos* The position, at which *ins* should be inserted in *str*.
- ins* A uint16_t string. This is *not* a wchar_t string.
- inslen* The length of *ins* or -1 if it is zero-terminated.

Returns:

NULL on failure or a pMath String. You must destroy it.

If *str* is NULL, it is assumed to be the empty string.

7.5.3.13 PMATH_API pmath_string_t pmath_string_insert (pmath_string_t *str*, int *inspos*, pmath_string_t *ins*) [inherited]

Insert one pMath String into another pMath String.

Parameters:

str A pMath String or NULL. It will be freed.

inspos The position, at which *ins* should be inserted in *str*.

ins A pMath String or NULL. It will be freed.

Returns:

NULL on failure or a pMath String. You must destroy it.

7.5.3.14 PMATH_API pmath_string_t pmath_string_concat (pmath_string_t *prefix*, pmath_string_t *postfix*) [inherited]

Concatenate two pMath Strings.

Parameters:

prefix A pMath String. It will be freed.

postfix A pMath String. It will be freed.

Returns:

NULL on failure or a pMath String that consists of *prefix* followed by *postfix*. You must destroy it.

If one of the two strings is NULL, the other string will be returned.

7.5.3.15 PMATH_API pmath_string_t pmath_string_part (pmath_string_t *string*, int *start*, int *length*) [inherited]

Extract a substring of a pMath String.

Parameters:

string A pMath String. It will be freed.

start the substring's start index.

length the substring's length or -1 for the whole substring beginng at start.

Returns:

NULL on failure or a pMath String.

If *start* or *start+length* are out of bounds, thy will be truncated, the the resulting string's length is not neccesaryly *length*.

7.5.3.16 PMATH_API `const uint16_t * pmath_string_buffer (pmath_string_t string)` [inherited]

Get a string's buffer for reading.

Parameters:

string A string. It remains valid after the function call, so you have to destroy it manually.

Returns:

A pointer to the string's buffer. This buffer is guaranteed to be `pmath_string_length(str) * sizeof(uint16_t)` bytes long.

Do not forget that pMath strings are not zero-terminated.

7.5.3.17 PMATH_API `int pmath_string_length (pmath_string_t string)` [inherited]

Get a string's length.

Parameters:

string A string. It remains valid after the function call, so you have to destroy it manually.

Returns:

The length (in `uint16_t` characters) of the string. It is never negative.

7.5.3.18 PMATH_API `pmath_bool_t pmath_string_equals_latin1 (pmath_string_t string, const char * latin1)` [inherited]

Compare a pMth sting with a C string.

Parameters:

string A string. It wont be freed.

latin1 A C string (zero terminated).

Returns:

Whether the two string are equals.

This function is a short form for

```
tmp = PMATH_C_STRING(latin1);
result = pmath_equals(string, tmp);
pmath_unref(tmp);
```

7.6 Symbols

Symbol objects in pMath.

Data Structures

- class `pmath_symbol_t`
The Symbol class.

Typedefs

- typedef `pmath_t(* pmath_builtin_func_t)(pmath_expr_t expr)`
Prototype of a built-in function.
- typedef int `pmath_symbol_attributes_t`
The (bitset) type of symbol attributes.

Enumerations

- enum `pmath_code_usage_t`
*Constants saying when to call a binded function. May *f* be the pMath symbol.*

Functions

- PMATH_API `pmath_symbol_t pmath_symbol_builtin` (int index)
Get a builtin symbol object.
- PMATH_API `pmath_bool_t pmath_register_code` (`pmath_symbol_t` symbol, `pmath_builtin_func_t` func, `pmath_code_usage_t` usage)
Bind a pMath symbol to some native code.
- PMATH_API `pmath_bool_t pmath_register_approx_code` (`pmath_symbol_t` symbol, `pmath_t(*func)(pmath_t, double, double)`)
Bind a pMath symbol to some native code for approximation.
- PMATH_API void `pmath_symbol_remove` (`pmath_symbol_t` symbol)
Remove a symbol completely from the system.
- PMATH_API `pmath_symbol_t pmath_symbol_iter_next` (`pmath_symbol_t` old)
Iterate through the global symbol table.
- PMATH_API `pmath_symbol_t pmath_symbol_t::pmath_symbol_get` (`pmath_string_t` name, `pmath_bool_t` create)
Get a symbol by its fully qualified name.

- PMATH_API `pmath_symbol_t` `pmath_symbol_t::pmath_symbol_create_temporary` (`pmath_string_t` name, `pmath_bool_t` unique)
Create a new temporary symbol.
- PMATH_API `pmath_symbol_t` `pmath_symbol_t::pmath_symbol_find` (`pmath_string_t` name, `pmath_bool_t` create)
Find a symbol in the current namespace search path.
- PMATH_API `pmath_string_t` `pmath_symbol_t::pmath_symbol_name` (`pmath_symbol_t` symbol)
Get a symbol's name.
- PMATH_API `pmath_symbol_attributes_t` `pmath_symbol_t::pmath_symbol_get_attributes` (`pmath_symbol_t` symbol)
Get a symbol's attributes.
- PMATH_API `void` `pmath_symbol_t::pmath_symbol_set_attributes` (`pmath_symbol_t` symbol, `pmath_symbol_attributes_t` attr)
Set a symbol's attributes.
- PMATH_API `pmath_t` `pmath_symbol_t::pmath_symbol_get_value` (`pmath_symbol_t` symbol)
Get a symbol's value.
- PMATH_API `void` `pmath_symbol_t::pmath_symbol_set_value` (`pmath_symbol_t` symbol, `pmath_t` value)
Set a symbol's value.
- PMATH_API `void` `pmath_symbol_t::pmath_symbol_synchronized` (`pmath_symbol_t` symbol, `pmath_callback_t` callback, `void *data`)
Execute a function synchronized to a symbol.
- PMATH_API `void` `pmath_symbol_t::pmath_symbol_update` (`pmath_symbol_t` symbol)
Update a symbol manually.

7.6.1 Detailed Description

Symbol objects in pMath.

7.6.2 Typedef Documentation

7.6.2.1 `typedef pmath_t(* pmath_builtin_func_t)(pmath_expr_t expr)`

Prototype of a built-in function.

Parameters:

expr An expression. The function must free it.

Returns:

Any pMath object.

7.6.2.2 typedef int pmath_symbol_attributes_t

The (bitset) type of symbol attributes.

A pMath symbol (here called 'sym') can have one or more of the following values (concatenated with "|"):

- `PMATH_SYMBOL_ATTRIBUTE_PROTECTED`
Any assignment to sym will fail.
- `PMATH_SYMBOL_ATTRIBUTE_HOLDFIRST`
When evaluating 'sym(a,b,...)', the first argument (a) will not be evaluated automatically.
- `PMATH_SYMBOL_ATTRIBUTE_HOLDREST`
When evaluating 'sym(a,b,...)' all the arguments b,... will not be evaluated automatically.
- `PMATH_SYMBOL_ATTRIBUTE_HOLDALL`
combines `HOLDFIRST` and `HOLDREST`.
- `PMATH_SYMBOL_ATTRIBUTE_SYMMETRIC`
An expression 'sym(a,b,...)' will be sorted automatically and thus $\text{sym}(a,b) = \text{sym}(b,a)$.
- `PMATH_SYMBOL_ATTRIBUTE_ASSOCIATIVE`
An expression 'sym(...,sym(a,...,z),...)' will be flattened automatically to $\text{sym}(...,a,...,z,...)$.
- `PMATH_SYMBOL_ATTRIBUTE_NHOLDFIRST`
The first argument (a) of 'sym(a,b,...)' will not be affected by `Approximate(sym(a,b,...))`.
- `PMATH_SYMBOL_ATTRIBUTE_NHOLDREST`
All the argument 'b,...' in 'sym(a,b,...)' will not be affected by `Approximate(sym(a,b,...))`.
- `PMATH_SYMBOL_ATTRIBUTE_NHOLDALL`
combines `NHOLDFIRST` and `NHOLDREST`.
- `PMATH_SYMBOL_ATTRIBUTE_TEMPORARY`
The symbol sym will be deleted immediately when it is no longer referenced. It will be freed automatically (but not immediately), when there is no external reference to the symbol (just the symbol's own function definitions/...).
- `PMATH_SYMBOL_ATTRIBUTE_LISTABLE`
Any expression `sym(...)` will be threaded automatically over lists. (e.g. $\{a,b\} + \{c,d\}$ becomes $\{a+c, b+d\}$).
- `PMATH_SYMBOL_ATTRIBUTE_DEEPHOLDALL` The arguments 'a,...' in an expression 'sym(...)(a,...)' will not be evaluated automatically.
- `PMATH_SYMBOL_ATTRIBUTE_HOLDALLCOMPLETE`
Like `HOLDALL`, but in an expression 'sym(a,b,...)' all arguments (a,b,...) wont be touched even if they have the form 'eval(...)'. Additionally, rules for sym defined in one of its arguments (e.g. 'a: sym(a):= "hi"') wont be used.
- `PMATH_SYMBOL_ATTRIBUTE_ONEIDENTITY`
Used for pattern matching (in combination with `ASSOCIATIVE`) to say that 'sym(x)' matches x. Note that it does not automatically evaluate 'sym(x)' to x.

- `PMATH_SYMBOL_ATTRIBUTE_THREADLOCAL`

The symbol's value is local to the current thread. That means, an assignment to `sym` in one thread wont affect it in another thread.

- `PMATH_SYMBOL_ATTRIBUTE_NUMERICFUNCTION`

'`sym(x,...)`' is numeric if all the arguments are numeric.

- `PMATH_SYMBOL_ATTRIBUTE_READPROTECTED` '`??sym`' wont print out the value/function definitions for `sym`.

7.6.3 Enumeration Type Documentation

7.6.3.1 `enum pmath_code_usage_t`

Constants saying when to call a binded function. May `f` be the pMath symbol.

- `PMATH_CODE_USAGE_DOWNCALL` Call binded function when evaluating '`f(...)`'
- `PMATH_CODE_USAGE_SUBCALL` Call binded function when evaluating '`f(...)(...)`'
- `PMATH_CODE_USAGE_UPCALL` Call binded function when evaluating '`g(...,f,...)`' or '`g(..., f(...), ...)`'

These use cases correspond to the `DownRules()`, `SubRules()` and `UpRules()` of a symbol.

See also:

[pmath_register_code](#)

7.6.4 Function Documentation

7.6.4.1 `PMATH_API pmath_symbol_t pmath_symbol_builtin (int index)`

Get a builtin symbol object.

Parameters:

index The symbols unique index.

Returns:

The builtin symbol. This is not a copy. You must not destroy it with e.g. [pmath_unref\(\)](#).

When you want to use the returned symbol, [pmath_ref\(\)](#) it first. Normaly, you do not call this function directly but use one of the `PMATH_SYMBOL_XXX` macros instead, where `XXX` is the uppercase equivalent of the corresponding pMath symbol name, e.g. `PMATH_SYMBOL_LIST`.

There might be more references (e.g. on the stack or in other thread's local variable tables), so it is possible that the symbol still exists in the system.

Note that all builtin symbols (the `PMATH_SYMBOL_XXX`) are also referenced in a separate list and so cannot be removed completely from the system. However, their appearances in all other places will be removed. So this is a very dangerous function.

7.6.4.5 **PMATH_API** `pmath_symbol_t` `pmath_symbol_iter_next` (`pmath_symbol_t` *old*)

Iterate through the global symbol table.

Parameters:

old The previous symbol. It will be freed.

Returns:

The next symbol.

To actually iterate through the whole list, use the following pattern:

```
pmath_symbol_t iter = pmath_ref(PMATH_SYMBOL_LIST);
do{
    ... loop body here ...

    iter = pmath_symbol_iter_next(iter);
}while(iter && iter != PMATH_SYMBOL_LIST);
pmath_unref(iter);
```

7.6.4.6 **PMATH_API** `pmath_symbol_t` `pmath_symbol_get` (`pmath_string_t` *name*, `pmath_bool_t` *create*) [*inherited*]

Get a symbol by its fully qualified name.

Parameters:

name The symbol's name including its namespace. It will be freed.

create Whether to create a new symbol, if none was found.

Returns:

NULL or a symbol called *name* that must be destroyed with [pmath_unref\(\)](#).

7.6.4.7 **PMATH_API** `pmath_symbol_t` `pmath_symbol_create_temporary` (`pmath_string_t` *name*, `pmath_bool_t` *unique*) [*inherited*]

Create a new temporary symbol.

Parameters:

name The base name of the temporary symbol. It will be freed.

unique Whether to add a unique number to the symbol name.

Returns:

A new pMath Symbol. You must destroy it with [pmath_unref\(\)](#). It has the Temporary attribute.

the name of the returned symbol is of the form name\$nnn (or name\$ if unique is false)

If name already has the form "sym\$nnn" or "sym\$", the function acts as if name would be simply "sym".

If there already exists a symbol with the generated name, that symbol will be returned and its attributes will be set to Temporary before.

7.6.4.8 PMATH_API pmath_symbol_t pmath_symbol_find (pmath_string_t name, pmath_bool_t create) [inherited]

Find a symbol in the current namespace search path.

Parameters:

name The symbol's name. It will be freed.

create Whether to create a new symbol, if none was found.

Returns:

NULL or a symbol called name that must be destroyed with [pmath_unref\(\)](#).

7.6.4.9 PMATH_API pmath_string_t pmath_symbol_name (pmath_symbol_t symbol) [inherited]

Get a symbol's name.

Parameters:

symbol A pMath symbol.

Returns:

The name of the symbol. You must destroy it with [pmath_unref\(\)](#).

7.6.4.10 PMATH_API pmath_symbol_attributes_t pmath_symbol_get_attributes (pmath_symbol_t symbol) [inherited]

Get a symbol's attributes.

Parameters:

symbol A pMath symbol. It wont be freed.

Returns:

The symbol's attributes.

**7.6.4.11 PMATH_API void pmath_symbol_set_attributes (pmath_symbol_t *symbol*,
pmath_symbol_attributes_t *attr*)** [inherited]

Set a symbol's attributes.

Parameters:

symbol A pMath symbol. It wont be freed.

attr The new attributes.

7.6.4.12 PMATH_API pmath_t pmath_symbol_get_value (pmath_symbol_t *symbol*)
[inherited]

Get a symbol's value.

Deprecated**Parameters:**

symbol A pMath symbol.

Returns:

The symbol's value. You must free it with [pmath_unref\(\)](#). Note that not every object is evaluable (e.g. [Custom Objects](#)).

7.6.4.13 PMATH_API void pmath_symbol_set_value (pmath_symbol_t *symbol*, pmath_t *value*)
[inherited]

Set a symbol's value.

Deprecated**Parameters:**

symbol A pMath symbol. It wont be freed

value The new value. It will be freed.

This function ignores the Protected-attribute. You should only use it during symbol initialization and/or when you want to store non-evaluatable values in a symbol. In all other cases, evaluate an expression with the head PMATH_SYMBOL_ASSIGN or PMATH_SYMBOL_ASSIGNDELAYED.

7.6.4.14 PMATH_API void pmath_symbol_synchronized (pmath_symbol_t *symbol*, pmath_callback_t *callback*, void **data*) [inherited]

Execute a function synchronized to a symbol.

Deprecated

Parameters:

symbol The symbol to lock. It wont be freed.

callback The function to be executed when the symbol is locked.

data A pointer that will be passed to callback.

See also:

[Multithreading with pMath](#)

7.6.4.15 PMATH_API void pmath_symbol_update (pmath_symbol_t *symbol*) [inherited]

Update a symbol manually.

Parameters:

symbol A pMath symbol.

You normally do not have to call this, since every change in a symbol yields an update. But there are some situations where you might to update it manually. The update mechanism is an optimization. Any expresseion or symbol, that is up to date while evaluation, wont be evaluated again. After an evaluation, expressions are updated automatically.

7.7 C++ Binding

7.7.1 Detailed Description

There exists a thin layer to easily use pMath with C++. This is usably prefreable over the C API because it handles reference counting/type checking automatically and leads to less "boilerplate code"

To use it, simply include `<pmath-cpp.h>`. The classes are in the `pmath` namespace.

This namespace also containts numerous helper functions to easily construct expression trees.

Todo

Document the Expr helper functions.

7.8 Parsing Code

Translating pMath code or boxes to pMath objects.

Data Structures

- class `pmath_span_array_t`
Internal flat representaion of spans.
- class `pmath_span_t`
*Represents a span in a *span-array*.*

Defines

- `#define PMATH_RUN(code)`
Execute some pMath code.
- `#define PMATH_RUN_ARGS(code, format,...)`
Execute some pMath code with arguments.
- `#define PMATH_CHAR_INVISIBLECALL 0x2061`
The Function application character.
- `#define PMATH_CHAR_VECTOR 0x21C0`
The arrow above names to indicate a vector.
- `#define PMATH_CHAR_RULE 0x2192`
The " \rightarrow " operator.
- `#define PMATH_CHAR_RULEDELAYED 0x29F4`
The ";>" operator.
- `#define PMATH_CHAR_ASSIGN 0x2254`
The ":@" operator.
- `#define PMATH_CHAR_ASSIGNDELAYED 0x2A74`
The "::=" operator.
- `#define PMATH_CHAR_INTEGRAL_D 0x2146`
The integral "d".
- `#define PMATH_CHAR_PIECEWISE 0xF361`
The left curly bracket for cases.
- `#define PMATH_CHAR_ALIASDELIMITER 0xF764`
The character inserted by Richmath with ESCAPE or CAPSLOCK.
- `#define PMATH_CHAR_ALIASINDICATOR 0xF768`

A character that looks like `PMATH_CHAR_ALIASDELIMITER` but has no effect.

- `#define PMATH_CHAR_LEFT_BOX 0xFF9`
Start of box code inside a string.
- `#define PMATH_CHAR_RIGHT_BOX 0xFFB`
End of box code inside a string.
- `#define PMATH_CHAR_BOX 0xFDD0`
Represents a box.
- `#define PMATH_CHAR_PLACEHOLDER 0xFFFD`
The Placeholder character. In richmath, type CAPSLOCK pl CAPSLOCK to insert it.

Enumerations

- `enum pmath_token_t`
Token classes known in the pMath language.

Functions

- `PMATH_API pmath_span_array_t * pmath_spans_from_string (pmath_string_t *code, pmath_string_t(*line_reader)(void *), pmath_bool_t(*subsuperscriptbox_at_index)(int, void *), pmath_string_t(*underoverscriptbox_at_index)(int, void *), void(*error)(pmath_string_t, int, void *, pmath_bool_t), void *data)`
Parses pMath code to a span array.
- `PMATH_API pmath_t pmath_boxes_from_spans (pmath_span_array_t *spans, pmath_string_t string, pmath_bool_t parseable, pmath_t(*box_at_index)(int, void *), void *data)`
Convert a span-array with the according code to boxed form.
- `PMATH_API pmath_span_array_t * pmath_spans_from_boxes (pmath_t boxes, pmath_string_t *result_string, void(*make_box)(int, pmath_t, void *), void *data)`
Convert boxed form back to span-array and code.
- `PMATH_API pmath_token_t pmath_token_analyse (const uint16_t *str, int len, int *prec)`
Analyse a token.
- `PMATH_API int pmath_token_prefix_precedence (const uint16_t *str, int len, int defprec)`
Give the prefix operator precedence for a token.
- `static PMATH_INLINE pmath_bool_t pmath_token_maybe_first (pmath_token_t tok)`
Test whether a token may be the first token in a subexpression.
- `static PMATH_INLINE pmath_bool_t pmath_token_maybe_rest (pmath_token_t tok)`
Test whether a token need not be the first token in a subexpression.
- `static PMATH_INLINE pmath_bool_t pmath_char_is_left (uint16_t ch)`

Test if a unicode character is a left bracket.

- static PMATH_INLINE uint16_t `pmath_right_fence` (uint16_t left)
Get the corresponding right bracket to a given left bracket or 0.
- static PMATH_INLINE pmath_bool_t `pmath_char_is_right` (uint16_t ch)
Test if a unicode character is a right bracket.
- static PMATH_INLINE pmath_bool_t `pmath_char_is_name` (uint16_t ch)
Test if a unicode character can be the start of an identifier/name.
- static PMATH_INLINE pmath_bool_t `pmath_char_is_integral` (uint16_t ch)
Test if a unicode character is an integral.
- static PMATH_INLINE pmath_bool_t `pmath_token_maybe_bigop` (pmath_token_t tok)
Test if a token may be a big operator.
- static PMATH_INLINE pmath_bool_t `pmath_char_maybe_bigop` (uint16_t ch)
Test if a unicode character may be a big operation, e.g. Union, Sum.
- static PMATH_INLINE pmath_bool_t `pmath_char_is_digit` (uint16_t ch)
Test if a unicode character is a digit '0' - '9'.
- static PMATH_INLINE pmath_bool_t `pmath_char_is_36digit` (uint16_t ch)
Test if a unicode character is a base-36 digit '0' - '9', 'a' - 'z', 'A' - 'Z'.
- static PMATH_INLINE pmath_bool_t `pmath_char_is_basedigit` (int base, uint16_t ch)
Test if in a given base, a unicode character is a digit.
- static PMATH_INLINE pmath_bool_t `pmath_char_is_hexdigit` (uint16_t ch)
Test if a unicode character is a hexadecimal digit.
- PMATH_API void `pmath_span_array_t::pmath_span_array_free` (pmath_span_array_t *spans)
Destroy a span-array and all its spans.
- PMATH_API int `pmath_span_array_t::pmath_span_array_length` (pmath_span_array_t *spans)
Get a span-array's length.
- PMATH_API pmath_bool_t `pmath_span_array_t::pmath_span_array_is_token_end` (pmath_span_array_t *spans, int pos)
Test the token-end-flag at an index.
- PMATH_API pmath_bool_t `pmath_span_array_t::pmath_span_array_is_operator_start` (pmath_span_array_t *spans, int pos)
Test the operator-start-flag at an index.
- PMATH_API pmath_span_t * `pmath_span_array_t::pmath_span_at` (pmath_span_array_t *spans, int pos)
Get a span starting at an index.

- PMATH_API `pmath_span_t * pmath_span_t::pmath_span_next (pmath_span_t *span)`
Get the next-shorter span starting at the same position.
- PMATH_API `int pmath_span_t::pmath_span_end (pmath_span_t *span)`
Get end of a span.
- PMATH_API `pmath_t pmath_string_t::pmath_string_expand_boxes (pmath_string_t s)`
Expand a string that contains boxes to a list of Strings and Boxes.
- PMATH_API `pmath_t pmath_string_t::pmath_parse_string (pmath_string_t code)`
Parse a string to an expression.
- PMATH_API `pmath_t pmath_string_t::pmath_parse_string_args (const char *code, const char *format,...)`
Parse a string with additional arguments to an expression.

7.8.1 Detailed Description

Translating pMath code or boxes to pMath objects.

The pMath language supports standard mathematical notation (such as sums, ...). Therefor, code can be given as Boxes.

7.8.2 Example

The boxed form of $\sum_{i=1}^n f(i)$ is

```
{UnderoverscriptBox("\u2211", {"i", "=", "1"}, "n"), {"f", "(", "i",
") "}}
```

or

```
{{"\u2211", SubsuperscriptBox({"i", "=", "1"}, "n"), {"f", "(", "i",
") "}}
```

(U+2211 is the Unicode character "N-ARY SUMMATION").

It will be translated to `HoldComplete(Sum(f(i), i->1..n))` by `System`BoxesToExpression`.

Front-ends have to convert their own representation of the code to the boxed form before parsing.

7.8.3 Define Documentation

7.8.3.1 #define PMATH_RUN(code)

Value:

```
pmath_unref( \
  pmath_evaluate( \
    pmath_parse_string( \
      PMATH_C_STRING(code))) )
```

Execute some pMath code.

Parameters:

code The code as a C string (zero terminated).

7.8.3.2 #define PMATH_RUN_ARGS(code, format, ...)

Value:

```
pmath_unref( \
    pmath_evaluate( \
        pmath_parse_string_args( \
            (code), (format), __VA_ARGS__) ) )
```

Execute some pMath code with arguments.

Parameters:

code The code as a C string.

format The argument's type format string.

... The arguments.

See [pmath_build_value\(\)](#) for the meaning of *format* and ...

7.8.4 Function Documentation

7.8.4.1 PMATH_API pmath_span_array_t* pmath_spans_from_string (pmath_string_t * *code*, pmath_string_t*(void *) *line_reader*, pmath_bool_t*(int, void *) *subsuperscriptbox_at_index*, pmath_string_t*(int, void *) *underoverscriptbox_at_index*, void*(pmath_string_t, int, void *, pmath_bool_t) *error*, void * *data*)

Parses pMath code to a span array.

Parameters:

code A pointer to a pMath string.

line_reader A function to be called, when there is more input needed. Its result will be appended to *code.

subsuperscriptbox_at_index A function that returns TRUE iff at a given position in the code (indicated by the PMATH_CHAR_BOX character) is a SubscriptBox, SuperscriptBox or SubsuperscriptBox.

underoverscriptbox_at_index Iff there is an UnderscriptBox, OverscriptBox or UnderoverscriptBox at a given position in the code (indicated by the PMATH_CHAR_BOX character) its base (middle part of UnderoverscriptBox) should be returned by this function, otherwise NULL should be returned.

error A function that will be called on syntax errors. The first argument is `*code`. It must not be freed. The second argument is the position in the code. The third argument is `data`. The fourth argument is TRUE if the error is critical and FALSE if it is just a warning (Syntax::new!) This function is optional, if it is NULL, no messages will be generated during the scanning.

data An arbitrary pointer, that will be provided as the last argument to the callback functions.

Returns:

A span-array that can be used by `pmath_boxes_from_spans` to convert the code to boxed form, which, in turn, is used by `System'BoxesToExpression()`. The span-array must be freed with `pmath_span_array_free()` when it is no longer needed.

7.8.4.2 PMATH_API `pmath_t` `pmath_boxes_from_spans` (`pmath_span_array_t` * *spans*, `pmath_string_t` *string*, `pmath_bool_t` *parseable*, `pmath_t`(*)(`int`, `void` *) *box_at_index*, `void` * *data*)

Convert a span-array with the according code to boxed form.

Parameters:

spans A span-array. It can be obtained by `pmath_spans_from_string()` or `pmath_spans_from_boxes()`.

string The corresponding code to *span*. It wont be freed.

parseable Whether whitespace and comments should be skipped or not.

box_at_index A function that returns the box at a given position (indicated by the PMATH_CHAR_BOX character). This function will be called (at most) one time for every box and in their order of appearance.

data A pointer that will be provided as the last argument to *box_at_index*.

Returns:

A pMath object representing the boxed form. It must be freed.

7.8.4.3 PMATH_API `pmath_span_array_t`* `pmath_spans_from_boxes` (`pmath_t` *boxes*, `pmath_string_t` * *result_string*, `void`(*)(`int`, `pmath_t`, `void` *) *make_box*, `void` * *data*)

Convert boxed form back to span-array and code.

Parameters:

boxes A pMath object representing the boxed form.

result_string A pointer where the resulting code will go to. Its previous value is ignored.

make_box A function that converts a boxed form (pMath object) to an actual box. It must free this object (the second argument).

data A pointer that will be provided to *make_box* as the last argument.

Returns:

A span-array. It must be freed with `pmath_span_array_free()` when it is no longer needed.

7.8.4.4 PMATH_API pmath_token_t pmath_token_analyse (const uint16_t * *str*, int *len*, int * *prec*)

Analyse a token.

Parameters:

str A UTF16-string.

len The length (in uint16_t-s) of the token *str*.

prec Optional address, where to store the default operator precedence for the token.

Returns:

The associated token class.

7.8.4.5 PMATH_API int pmath_token_prefix_precedence (const uint16_t * *str*, int *len*, int *defprec*)

Give the prefix operator precedence for a token.

Parameters:

str A UTF16-string.

len The length (in uint16_t-s) of the token *str*.

defprec The default operator precedence as given by [pmath_token_analyse\(\)](#)

Returns:

The prefix operator precedence.

7.8.4.6 static PMATH_INLINE pmath_bool_t pmath_token_maybe_first (pmath_token_t *tok*) [static]

Test whether a token may be the first token in a subexpression.

Parameters:

tok A token class.

Returns:

Whether *tok* may start a new subexpression

7.8.4.7 `static PMATH_INLINE pmath_bool_t pmath_token_maybe_rest (pmath_token_t tok)`
[static]

Test whether a token need not be the first token in a subexpression.

Parameters:

tok A token class.

Returns:

Whether *tok* may reside inside a subexpression.

7.8.4.8 `PMATH_API void pmath_span_array_free (pmath_span_array_t * spans)`
[inherited]

Destroy a span-array and all its spans.

Parameters:

spans The span-array.

7.8.4.9 `PMATH_API int pmath_span_array_length (pmath_span_array_t * spans)`
[inherited]

Get a span-array's length.

Parameters:

spans The span-array.

Returns:

Its length or 0 if it's NULL.

7.8.4.10 `PMATH_API pmath_bool_t pmath_span_array_is_token_end (pmath_span_array_t *
spans, int pos)` [inherited]

Test the token-end-flag at an index.

Parameters:

spans The span-array.

pos The position. Must be between 0 and `pmath_span_array_length(spans) - 1`.

Returns:

Whether a token ends at the specified position.

7.8.4.11 PMATH_API pmath_bool_t pmath_span_array_is_operator_start (pmath_span_array_t * *spans*, int *pos*) [inherited]

Test the operator-start-flag at an index.

Parameters:

spans The span-array.

pos The position. Must be between 0 and `pmath_span_array_length(spans) - 1`.

Returns:

Whether an operator starts at the specified position.

7.8.4.12 PMATH_API pmath_span_t * pmath_span_at (pmath_span_array_t * *spans*, int *pos*) [inherited]

Get a span starting at an index.

Parameters:

spans The span-array.

pos The position. Must be between 0 and `pmath_span_array_length(spans) - 1`.

Returns:

The largest span stating at *pos* or NULL if there is no span.

7.8.4.13 PMATH_API pmath_span_t * pmath_span_next (pmath_span_t * *span*) [inherited]

Get the next-shorter span starting at the same position.

Parameters:

span A span.

Returns:

The next-shorter span stating at *pos* or NULL if there is no span.

7.8.4.14 PMATH_API int pmath_span_end (pmath_span_t * *span*) [inherited]

Get end of a span.

Parameters:

span A span.

Returns:

The last index which is covered by the span.

7.8.4.15 PMATH_API pmath_t pmath_string_expand_boxes (pmath_string_t s) [related, inherited]

Expand a string that contains boxes to a list of Strings and Boxes.

Parameters:

s The string to be expanded. It will be freed.

Returns:

A string if there is nothing to expand or an expression representing *s* as boxes.

7.8.4.16 PMATH_API pmath_t pmath_parse_string (pmath_string_t code) [related, inherited]

Parse a string to an expression.

Parameters:

code A pMath String representing the code. It will be freed.

Returns:

A pMath object.

This function returns `Release(BoxesToExpression(StringToBoxes("code")))`, but does not evaluate this released result.

7.8.4.17 PMATH_API pmath_t pmath_parse_string_args (const char * code, const char * format, ...) [related, inherited]

Parse a string with additional arguments to an expression.

Parameters:

code A pMath String representing the code. It will be freed.

format A format string for the arguments.

... The additional arguments.

Returns:

A pMath object.

This function is a short hand for

1. assigning `pmath_build_value(format, ...)` to the symbol `$ParserArguments`
2. then calling `pmath_parse_string(PMATH_C_STRING(code))` and
3. restoring the old value of `$ParserArguments` before
4. returning the result of the `pmath_parse_string`-call.

[pmath_build_value](#)
[pmath_parse_string](#)

7.9 General Purpose Types

Useful type definitions that do not fit into any other category.

Defines

- `#define FALSE ((pmath_bool_t)0)`
The FALSE value for `pmath_bool_t`.
- `#define TRUE (!FALSE)`
The TRUE value for `pmath_bool_t`.

Typedefs

- `typedef char pmath_bool_t`
A boolean type.
- `typedef void(* pmath_callback_t)(void *)`
A general callback function.
- `typedef void(* pmath_write_func_t)(void *user, const uint16_t *data, int len)`
A UCS-2 writer callback function.
- `typedef void(* pmath_write_unichar_func_t)(void *user, uint32_t ch)`
A callback function to write a single unicode character.

7.9.1 Detailed Description

Useful type definitions that do not fit into any other category.

7.9.2 Typedef Documentation

7.9.2.1 typedef char pmath_bool_t

A boolean type.

C does not define a boolean type, so we do it here for code clarity. The constants TRUE and FALSE can be used as return values for pmath_bool_t, but do not test on these. E.g. use if(test)... instead of if(test == TRUE)... but return FALSE; instead of return 0;

7.9.2.2 typedef void(* pmath_callback_t)(void *)

A general callback function.

This is used in various places where a callback function is needed, that does not only work with pMath objects.

7.9.2.3 typedef void(* pmath_write_func_t)(void *user, const uint16_t *data, int len)

A UCS-2 writer callback function.

The to-be-written data is not zero-terminated.

7.10 Atomic Operations

Using atomic operations (independent of the rest of the library).

Functions

- `intptr_t pmath_atomic_fetch_add (intptr_t volatile *atom, intptr_t delta)`
Add a value to another.
- `intptr_t pmath_atomic_fetch_set (intptr_t volatile *atom, intptr_t new_value)`
Exchange a value.
- `intptr_t pmath_atomic_fetch_compare_and_set (intptr_t volatile *atom, intptr_t old_value, intptr_t new_value)`
Exchange a value if it equals another value.
- `pmath_bool_t pmath_atomic_compare_and_set (intptr_t volatile *atom, intptr_t old_value, intptr_t new_value)`
Exchange a value if it equals another value.
- `pmath_bool_t pmath_atomic_compare_and_set_2 (intptr_t volatile *atom, intptr_t old_value_fst, intptr_t old_value_snd, intptr_t new_value_fst, intptr_t new_value_snd)`
Exchange two values value if they equal another two values.

- `pmath_bool_t pmath_atomic_have_cas2` (void)
Check, whether the CPU supports `pmath_atomic_compare_and_set_2()`.
- void `pmath_atomic_barrier` (void)
Insert an explicit memory barrier.
- void `pmath_atomic_lock` (intptr_t volatile *atom)
Try to acquire a lock.
- void `pmath_atomic_unlock` (intptr_t volatile *atom)
Release a previously acquired lock.
- void `pmath_atomic_loop_nop` (void)

7.10.1 Detailed Description

Using atomic operations (independent of the rest of the library).

pMath provides a collection of functions/macros to do atomic operations. This part of the library is completely independent of the rest of pMath. To use atomic operations, `#include <pmath-util/concurrency/atomic.h>`. You do not have to link to an additional library.

At the moment, supported compilers are GCC and Microsoft Visual C++.

On some platforms, the atomic operations are implemented as inline functions with inline assembler (currently GCC older than 4.x). On other platforms, macros and compiler intrinsic functions (GCC 4.x, MSVC) are used.

- `qprof -> atomic_ops` library

7.10.3 Function Documentation

7.10.3.1 `intptr_t pmath_atomic_fetch_add (intptr_t volatile * atom, intptr_t delta)`

Add a value to another.

Parameters:

atom A sizeof(void*) aligned pointer.

delta The difference between the new and the old value.

Returns:

The old value of **atom*.

This function increments **atom* atomically by *delta*. It has full memory barrier semantics.

7.10.3.2 `intptr_t pmath_atomic_fetch_set (intptr_t volatile * atom, intptr_t new_value)`

Exchange a value.

Parameters:

atom A sizeof(void*) aligned pointer.

new_value The new value of **atom*.

Returns:

The old value of **atom*.

This function sets **atom* to *new_value* and returns the old value atomically. It has full memory barrier semantics.

7.10.3.3 `intptr_t pmath_atomic_fetch_compare_and_set (intptr_t volatile * atom, intptr_t old_value, intptr_t new_value)`

Exchange a value if it equals another value.

Parameters:

atom A sizeof(void*) aligned pointer.

old_value The comparisor.

new_value The possible new value of **atom*.

Returns:

The old value of **atom*.

You should use `pmath_atomic_compare_and_set()` if you don't need the exact old value of **atom*, because this function might be non-existent on some systems. This function has acquire barrier semantics.

7.10.3.4 `pmath_bool_t pmath_atomic_compare_and_set (intptr_t volatile * atom, intptr_t old_value, intptr_t new_value)`

Exchange a value if it equals another value.

Parameters:

atom A sizeof(void*) aligned pointer.
old_value The comparator.
new_value The possible new value of *atom.

Returns:

Whether the exchange was performed.

This function compares *atom with *old_value* and iff both equal sets *atom to *new_value*, everything atomically and with acquire barrier semantics.

7.10.3.5 `pmath_bool_t pmath_atomic_compare_and_set_2 (intptr_t volatile * atom, intptr_t old_value_fst, intptr_t old_value_snd, intptr_t new_value_fst, intptr_t new_value_snd)`

Exchange two values value if they equal another two values.

Parameters:

**atom* A 2*sizeof(void*) aligned pointer to two values.
old_value_fst The first old value.
old_value_snd The second old value.
new_value_fst The possible new value of atom[0].
new_value_snd The possible new value of atom[1].

Returns:

Whether the exchange was performed or not.

This function compares *old_value_fst* with atom[0] and *old_value_snd* with atom[1]. If they equal, atom[0] is set to *new_value_fst* and atom[1] is set to *new_value_snd* and TRUE is returned. Otherwise, FALSE will be returned.

This function has acquire barrier semantics.

Note:

This function is not available on all Platforms. You must not call it if [pmath_atomic_have_cas2\(\)](#) returns FALSE.

7.10.3.6 `pmath_bool_t pmath_atomic_have_cas2 (void)`

Check, whether the CPU supports `pmath_atomic_compare_and_set_2()`.

Returns:

whether `pmath_atomic_compare_and_set_2()` is supported.

Note, that a call to `pmath_atomic_compare_and_set_2()` will crash your application on any platform that does not support the operation (e.g. pre-Pentiums, early AMD64).

7.10.3.7 `void pmath_atomic_lock (intptr_t volatile * atom)`

Try to acquire a lock.

Parameters:

atom The lock. A `sizeof(void*)` aligned pointer.

This function implements a spin lock. It has acquire barrier semantics. Use it with `pmath_atomic_unlock()`:

```
PMATH_DECLARE_ATOMIC (spin);  
...  
pmath_atomic_lock (&spin)  
... critical section ...  
pmath_atomic_unlock (&spin);
```

7.10.3.8 `void pmath_atomic_unlock (intptr_t volatile * atom)`

Release a previously acquired lock.

Parameters:

atom The lock. A `sizeof(void*)` aligned pointer.

See also:

[pmath_atomic_lock](#)

7.10.3.9 `void pmath_atomic_loop_nop (void)`

A no-operation for use in spin locks.

7.11 Thread Messaging

Sending messages to other threads.

Data Structures

- class `pmath_messages_t`
A message queue for interthread communication.

Functions

- PMATH_API `pmath_bool_t pmath_messages_t::pmath_is_message_queue (pmath_t obj)`
Test if an object is a message queue.
- PMATH_API `pmath_messages_t pmath_messages_t::pmath_thread_get_queue (void)`
Get the current thread's message queue.
- PMATH_API void `pmath_messages_t::pmath_thread_sleep (void)`
Send the current thread to sleep.
- PMATH_API void `pmath_messages_t::pmath_thread_wakeup (pmath_messages_t mq)`
Wake up another thread.
- PMATH_API void `pmath_messages_t::pmath_thread_send (pmath_messages_t mq, pmath_t msg)`
Asynchronously send a message to another thread.
- PMATH_API `pmath_t pmath_messages_t::pmath_thread_send_wait (pmath_messages_t mq, pmath_t msg, double timeout_seconds)`
Send a message to another thread and wait for the answer.
- PMATH_API void `pmath_messages_t::pmath_thread_send_delayed (pmath_messages_t mq, pmath_t msg, double seconds)`
Asynchronously send a message to a thread sometime in the future.

7.11.1 Detailed Description

Sending messages to other threads.

Every pMath thread has its own message queue. Other threads can send messages to such a queue and optionally wait for a result. Messages to any queue can also be registered for delivery at a later point in time.

Threads can go to sleep when they have no work to do. They will be awoken any time a message arrives to handle it.

Technical Note: Pending messages are handled any time `pmath_aborting()` is called, which happens periodically. For the pMath code, it looks like asynchronous signals, because messages can occur any time during the evaluation. But from the native code's point of view, messages are synchronous, because they can only occur during `pmath_aborting()`.

Note:

Message passing is not signal-safe. You must not send any messages from within a signal handler.

7.11.2 Function Documentation

7.11.2.1 PMATH_API `pmath_bool_t pmath_is_message_queue (pmath_t obj)` [related, inherited]

Test if an object is a message queue.

Parameters:

obj Any pMath object. It wont be freed.

Returns:

TRUE if the object is a valid message queue object ([pmath_messages_t](#)).

7.11.2.2 PMATH_API `pmath_messages_t pmath_thread_get_queue (void)` [related, inherited]

Get the current thread's message queue.

Returns:

A reference to the message queue or NULL on error. You must destroy it with [pmath_unref\(\)](#) when its no longer needed.

7.11.2.3 PMATH_API `void pmath_thread_sleep (void)` [related, inherited]

Send the current thread to sleep.

The thread will fall asleep until

- it receives a message or
- it is waken up with [pmath_thread_wakeup\(\)](#) or
- an abort-condition ([pmath_abort_please\(\)](#) or [pmath_throw\(\)](#)) is met *anywhere* in the system.

7.11.2.4 PMATH_API `void pmath_thread_wakeup (pmath_messages_t mq)` [related, inherited]

Wake up another thread.

Parameters:

mq The message queue associated with the sleeping thread. It wont be freed.

This function wakes up the thread that is associated with the message queue. It is safe to try to wake up threads, that are not sleeping.

7.11.2.5 PMATH_API void pmath_thread_send (pmath_messages_t *mq*, pmath_t *msg*) [related, inherited]

Asynchronously send a message to another thread.

Parameters:

mq The receivers message queue. It wont be freed.

msg The message. It will be freed.

The message will be evaluated by the receiver. This function returns immediately. If the receiver cannot handle the message (since it is dead or there is not enough memory), the message will be deleted.

7.11.2.6 PMATH_API pmath_t pmath_thread_send_wait (pmath_messages_t *mq*, pmath_t *msg*, double *timeout_seconds*) [related, inherited]

Send a message to another thread and wait for the answer.

Parameters:

mq The receivers message queue. It wont be freed.

msg The message. It will be freed.

timeout_seconds The maximum number of seconds tho wait for the answer. Use HUGE_VAL if you do not want a timeout.

Returns:

The result of pmath_evaluate(message) called by the receiver or PMATH_UNDEFINED in case of an error.

The message will be evaluated by the receiver. If the receiver cannot handle it (since it is dead or there is not enough memory), the message will be deleted.

The calling thread will fall asleep until

- it receives an answer to return or
- the message is deleted or
- the timeout is reached or
- another abort situation occurs in the calling thread (e.g. [pmath_abort_please\(\)](#) is called)

In the last two cases (timeout or abort), a the remote evaluation will be aborted.

Todo

Check, what happens if mq belongs to a parent thread.

7.11.2.7 PMATH_API void pmath_thread_send_delayed (pmath_messages_t *mq*, pmath_t *msg*, double *seconds*) [related, inherited]

Asynchronously send a message to a thread sometime in the future.

Parameters:

- mq* The receivers message queue. It wont be freed.
- msg* The message. It will be freed.
- seconds* The delay in seconds before the message will be delivered.

The message will be evaluated by the receiver. This function returns immediately. If the receiver cannot handle the message (since it is dead or there is not enough memory), the message will be deleted.

7.12 Multithreading with pMath

The Thread abstraction in pMath.

Data Structures

- class [pmath_threadlock_t](#)
A reentrant lock for threads.
- class [pmath_thread_t](#)
The Representation of a thread.

Functions

- PMATH_API [pmath_t](#) [pmath_thread_local_save](#) (pmath_t key, pmath_t value)
Store a thread/thread-local value.
- PMATH_API [pmath_t](#) [pmath_thread_local_load](#) (pmath_t key)
Load a thread/thread-local value.
- PMATH_API void [pmath_throw](#) (pmath_t exception)
Throw an exception.
- PMATH_API [pmath_t](#) [pmath_catch](#) (void)
Catch any exception.
- PMATH_API [pmath_bool_t](#) [pmath_aborting](#) (void)
Queries whether pMath was requested to abort the evaluation of the current thread.
- PMATH_API void [pmath_abort_please](#) (void)
Requests pMath to abort the current evaluation.
- PMATH_API void [pmath_suspend_all_please](#) (void)

Suspend all other threads. This function does not really suspend threads immediately. Any other thread, that calls `pmath_aborting()` (or `pmath_thread_aborting()`), will block until we call `pmath_resume_all()`.

- PMATH_API void `pmath_resume_all` (void)
Resume all other threads.
- PMATH_API void `pmath_threadlock_t::pmath_thread_call_locked` (`pmath_threadlock_t` *threadlock_ptr, `pmath_callback_t` callback, void *data)
Execute a function synchronized with a threadlock.
- PMATH_API `pmath_thread_t` `pmath_thread_t::pmath_thread_get_current` (void)
Get the current pMath thread.
- PMATH_API `pmath_thread_t` `pmath_thread_t::pmath_thread_get_parent` (`pmath_thread_t` thread)
Get a thread's direct parent.
- PMATH_API `pmath_bool_t` `pmath_thread_t::pmath_thread_is_parent` (`pmath_thread_t` parent, `pmath_thread_t` child)
Queries whether a thread is one of the parents of another.
- PMATH_API `pmath_bool_t` `pmath_thread_t::pmath_thread_aborting` (`pmath_thread_t` thread)
Queries whether pMath was requested to abort the evaluation of a specific thread or its parents.

7.12.1 Detailed Description

The Thread abstraction in pMath.

pMath stores several data local to a thread. Therefore, it maintains a `pmath_thread_t` in every operating system thread it runs on. Those `pmath_thread_t` variables are created and freed via `pmath_init()` and `pmath_done()` respectively. Thus, you have to call those two functions once in every thread that uses pMath functions (and abort the thread if `pmath_init()` fails).

pMath Threads can have parents. While one thread is running, its parent thread waits (for all its children) and is effectively immutable. This way, child threads can read their parent thread's local variables.

7.12.2 Synchronization

In other environments, you normally do synchronization with mutexes and the like. But if we did so, a deadlock could occur when a mutex is already locked by the parent thread, which in turn is waiting for its children to finish.

The solution is to use pMath threadlocks: You simply synchronize with a `pmath_symbol_t` through `pmath_symbol_synchronized()` or directly with a `pmath_threadlock_t` and `pmath_thread_call_locked()`. This is reentrant and locks execution to a given thread *and* its child threads. pMath cares about avoiding deadlocks behind the scenes.

Note that threadlocks are needed only if the synchronized code might create child threads or calls other code that utilizes thread locks. Threads might be created by `pmath_evaluate()` & co.

In other situations, you should use mutexes/semaphores from your operating system library or spinlocks (see `pmath_atomic_lock()` and `pmath_atomic_unlock()`), because they are much faster.

For some simple changes on global integer/pointer variables, you can use [Atomic Operations](#).

7.12.3 Function Documentation

7.12.3.1 PMATH_API pmath_t pmath_thread_local_save (pmath_t *key*, pmath_t *value*)

Store a thread/thread-local value.

Parameters:

key The key that can be used to obtain the value with `_pmath_thread_local_load()`. It wont be freed.
value The thread/thread-local value. It will be freed.

Returns:

`PMATH_UNDEFINED` or the previous value that was stored with the same key. You must destroy it.

Note that keys of the form ‘symboltag’ are used to store whether a message should be suppressed (value `PMATH_SYMBOL_OFF`) or not (value `NULL`).

All keys that are [magic numbers](#), have special meanings for `pmath_thread_local_save()`. You should not use them as the a key.

Keys which are only symbols are used for thread-local symbols (

See also:

[pmath_symbol_attributes_t](#)).

7.12.3.2 PMATH_API pmath_t pmath_thread_local_load (pmath_t *key*)

Load a thread/thread-local value.

Parameters:

key A key that was used to save the value with `_pmath_thread_local_save()` before. It wont be freed.

Returns:

`PMATH_UNDEFINED` or the stored value. You must destroy the it.

If there is nothing stored for key in the current thread, its parent threads are processed. If none of them stores something under ‘key’ and key is a symbol, The global value is used.

7.12.3.3 PMATH_API void pmath_throw (pmath_t *exception*)

Throw an exception.

Parameters:

exception The exception to be thrown. It will be freed. You cannot throw the [magic number](#) `PMATH_UNDEFINED`.

If there is already an uncought exception, this new exception is lost.

7.12.3.4 PMATH_API pmath_t pmath_catch (void)

Catch any exception.

Returns:

exception The exception to be thrown. If there is no exception available, PMATH_UNDEFINED will be returned.

If you cannot handle the exception, you can re-throw it with [pmath_throw\(\)](#).

7.12.3.5 PMATH_API pmath_bool_t pmath_aborting (void)

Queries whether pMath was requested to abort the evaluation of the current thread.

Returns:

Whether the user called [pmath_abort_please\(\)](#) or an exception was thrown or a time-out is passed.

7.12.3.6 PMATH_API void pmath_abort_please (void)

Requests pMath to abort the current evaluation.

This function is signal-safe.

See also:

[pmath_continue_after_abort\(\)](#)

7.12.3.7 PMATH_API void pmath_resume_all (void)

Resume all other threads.

See also:

[pmath_suspend_all_please](#)

7.12.3.8 PMATH_API void pmath_thread_call_locked (pmath_threadlock_t * *threadlock_ptr*, pmath_callback_t *callback*, void * *data*) [related, inherited]

Execute a function synchronized with a threadlock.

Parameters:

threadlock_ptr A pointer to the threadlock.

callback The function to be executed when the symbol is locked.

data A pointer that will be passed to callback.

All you have to do is initialize the threadlock `threadlock_ptr` points to with `NULL` before you call this function for the first time:

```
static pmath_threadlock_t lock = NULL;
...
pmath_thread_call_locked(&lock, my_callback, my_data);
```

To synchronize with a symbol, use [pmath_symbol_synchronized\(\)](#).

7.12.3.9 PMATH_API `pmath_thread_t pmath_thread_get_current (void)` [related, inherited]

Get the current pMath thread.

Returns:

A [pmath_thread_t](#). This is `NULL`, if you did not register the current thread to pMath via [pmath_init\(\)](#).

7.12.3.10 PMATH_API `pmath_thread_t pmath_thread_get_parent (pmath_thread_t thread)` [related, inherited]

Get a thread's direct parent.

Parameters:

thread A thread.

Returns:

The direct parent of thread. Usually `NULL`.

7.12.3.11 PMATH_API `pmath_bool_t pmath_thread_is_parent (pmath_thread_t parent, pmath_thread_t child)` [related, inherited]

Queries whether a thread is one of the parents of another.

Parameters:

parent A thread.

child A thread.

Returns:

`TRUE`, if parent is a parent thread of child or if `parent == child`. `FALSE` otherwise.

It is important to know that a parent thread is never executed in parallel with its children.

7.12.3.12 PMATH_API `pmath_bool_t` `pmath_thread_aborting` (`pmath_thread_t` *thread*) [related, inherited]

Queries whether pMath was requested to abort the evaluation of a specific thread or its parents.

Parameters:

thread A thread that should be tested.

Returns:

Whether the given thread should abort evaluation.

See also:

[pmath_aborting](#)

7.13 Debugging

Functions

- PMATH_API void [pmath_debug_print](#) (const char *fmt,...)
Print out a simple debug message.
- PMATH_API void [pmath_debug_print_object](#) (const char *pre, [pmath_t](#) obj, const char *post)
Print a pMath object to the debug log.

7.13.1 Detailed Description

These functions are for logging purposes. They default to ((void)0) unless PMATH_DEBUG_LOG is defined.

7.13.2 Function Documentation

7.13.2.1 PMATH_API void `pmath_debug_print` (const char **fmt*, ...)

Print out a simple debug message.

Parameters:

fmt A printf-compatible format string

... The variables to be printed as specified by format.

The format string and arguments are as in printf.

7.13.2.2 PMATH_API void pmath_debug_print_object (const char * *pre*, pmath_t *obj*, const char * *post*)

Print a pMath object to the debug log.

Parameters:

pre A string that should be printed before the object.

obj A pMath object. It wont be freed.

post A string that should be printed after the object.

7.14 File API

Unified API to access file or other memory content.

Data Structures

- class [pmath_binary_file_api_t](#)
Access functions for binary files.
- class [pmath_text_file_api_t](#)
Access functions for text files.

Enumerations

- enum [pmath_files_status_t](#) {
[PMATH_FILE_OK](#) = 0, [PMATH_FILE_INVALID](#) = 1,
[PMATH_FILE_ENDOFFILE](#) = 2, [PMATH_FILE_OTHERERROR](#) = 3,
[PMATH_FILE_RECURSIVE](#) = 4 }
The status of a file.

Functions

- PMATH_API [pmath_bool_t](#) [pmath_file_test](#) ([pmath_t](#) file, int properties)
Check whether a file supports a set of properties.
- PMATH_API [pmath_files_status_t](#) [pmath_file_status](#) ([pmath_t](#) file)
Get the current status of a readable file.
- PMATH_API [size_t](#) [pmath_file_read](#) ([pmath_t](#) file, void *buffer, [size_t](#) buffer_size, [pmath_bool_t](#) preserve_internal_buffer)
Read some bytes from a binary file.
- PMATH_API [pmath_string_t](#) [pmath_file_readline](#) ([pmath_t](#) file)
Read one line from a text file.

- PMATH_API void [pmath_file_set_textbuffer](#) ([pmath_t](#) file, [pmath_string_t](#) buffer)
Set a file's text buffer.
- PMATH_API size_t [pmath_file_write](#) ([pmath_t](#) file, const void *buffer, size_t buffer_size)
Write some bytes to a binary file.
- PMATH_API [pmath_bool_t](#) [pmath_file_writetext](#) ([pmath_t](#) file, const uint16_t *str, int len)
Write to a text file.
- PMATH_API void [pmath_file_flush](#) ([pmath_t](#) file)
Flush the output buffer of a writeable file.
- PMATH_API [pmath_bool_t](#) [pmath_file_write_object](#) ([pmath_t](#) file, [pmath_t](#) obj, [pmath_write_options_t](#) options)
Write an object to a text file.
- PMATH_API [pmath_bool_t](#) [pmath_file_set_binbuffer](#) ([pmath_t](#) file, size_t size)
Set a binary file's buffer size.
- PMATH_API void [pmath_file_manipulate](#) ([pmath_t](#) file, void(*type)(void *), void(*callback)(void *, void *), void *data)
Manipulate a file's internal representation.
- PMATH_API [pmath_bool_t](#) [pmath_file_close](#) ([pmath_t](#) file)
Closes a file.
- PMATH_API [pmath_symbol_t](#) [pmath_file_create_binary](#) (void *extra, void(*extra_destructor)(void *), [pmath_binary_file_api_t](#) *api)
Create a binary file object.
- PMATH_API [pmath_symbol_t](#) [pmath_file_create_text](#) (void *extra, void(*extra_destructor)(void *), [pmath_text_file_api_t](#) *api)
Create a text file object.
- PMATH_API [pmath_symbol_t](#) [pmath_file_create_text_from_binary](#) ([pmath_t](#) binfile, const char *encoding)
Create a text file object operating on a binary file.
- PMATH_API [pmath_symbol_t](#) [pmath_file_create_binary_buffer](#) (size_t mincapacity)
Create a byte-stream file object.
- PMATH_API size_t [pmath_file_binary_buffer_size](#) ([pmath_t](#) binfile)
Get The number of readable bytes in a binary buffer.
- PMATH_API void [pmath_file_binary_buffer_manipulate](#) ([pmath_t](#) binfile, void(*callback)(uint8_t *readable, uint8_t *writable, const uint8_t *end, void *closure), void *closure)
Manipulate the content of a binary buffer.

7.14.1 Detailed Description

Unified API to access file or other memory content.

A file is a [Symbol](#) (normally with attribute [PMATH_SYMBOL_ATTRIBUTE_TEMPORARY](#)) whose value is a special [Custom Object](#).

The output functions can operate on lists of files.

7.14.2 Enumeration Type Documentation

7.14.2.1 enum pmath_files_status_t

The status of a file.

See also:

[pmath_file_status\(\)](#)

Enumerator:

PMATH_FILE_OK No error.

PMATH_FILE_INVALID The object is no readable file.

PMATH_FILE_ENDOFFILE The (readable) file position is at the end.

PMATH_FILE_OTHERERROR There is another problem with the file.

PMATH_FILE_RECURSIVE The file is already locked by the current thread.

7.14.3 Function Documentation

7.14.3.1 PMATH_API pmath_bool_t pmath_file_test (pmath_t file, int properties)

Check whether a file supports a set of properties.

Parameters:

file A file object. It won't be freed.

properties File properties. See remarks section.

Returns:

TRUE iff the file supports all of the requested properties.

Remarks:

properties can be zero or more of the following values:

- **PMATH_FILE_PROP_READ**: The file is readable.
- **PMATH_FILE_PROP_WRITE**: The file is writeable.
- **PMATH_FILE_PROP_BINARY**: It is a binary file.
- **PMATH_FILE_PROP_TEXT**: It is a text file.

Lists of writeable files are writeable, too. Only Symbols can be readable files.

7.14.3.2 PMATH_API `pmath_files_status_t pmath_file_status (pmath_t file)`

Get the current status of a readable file.

Parameters:

file A readable file object. It wont be freed.

Returns:

`pmath_files_status_t` The current file status.

7.14.3.3 PMATH_API `size_t pmath_file_read (pmath_t file, void * buffer, size_t buffer_size, pmath_bool_t preserve_internal_buffer)`

Read some bytes from a binary file.

Parameters:

file A readable binary file object. It wont be freed.

buffer The read bytes will go here.

buffer_size The number of bytes you would like to read/size of *buffer*.

preserve_internal_buffer If TRUE, a subsequent call will get the same buffer content. If FALSE, the file pointer will be moved.

Returns:

Number of read bytes. This is never more than *buffer_size*. If *preserve_internal_buffer* is TRUE or in case of an error, this can be less than *buffer_size*.

7.14.3.4 PMATH_API `pmath_string_t pmath_file_readline (pmath_t file)`

Read one line from a text file.

Parameters:

file A readable text file object. It wont be freed.

Returns:

The next line in the file.

7.14.3.5 PMATH_API `void pmath_file_set_textbuffer (pmath_t file, pmath_string_t buffer)`

Set a file's text buffer.

Parameters:

file A readable text file. It wont be freed.

buffer A string. It should not contain any new line characters.

7.14.3.6 PMATH_API size_t pmath_file_write (pmath_t file, const void * buffer, size_t buffer_size)

Write some bytes to a binary file.

Parameters:

file A writeable binary file object. It wont be freed.

buffer The data to be written.

buffer_size The number of bytes to write/size of *buffer*.

Returns:

The number of written bytes. This is less than *buffer_size* in case of an error. If *file* is a list of files this is the smallest number of written bytes to the single files.

7.14.3.7 PMATH_API pmath_bool_t pmath_file_writetext (pmath_t file, const uint16_t * str, int len)

Write to a text file.

Parameters:

file A writeable text file object. It wont be freed.

str A UTF-16 string buffer. e.g. `pmath_string_buffer(some_text)`

len The number of `uint16_t` in the buffer. e.g. `pmath_string_length(some_text)`. This can be -1 if *str* is zero terminated.

Returns:

Whether the operation succeeded.

7.14.3.8 PMATH_API void pmath_file_flush (pmath_t file)

Flush the output buffer of a writeable file.

Parameters:

file A writeable binary file object. It wont be freed.

7.14.3.9 PMATH_API `pmath_bool_t` `pmath_file_write_object` (`pmath_t file`, `pmath_t obj`, `pmath_write_options_t options`)

Write an object to a text file.

Parameters:

- file* A writeable text file object. It wont be freed.
- obj* An object. It wont be freed.
- options* Some options defining the format.

Returns:

Whether the operation succeeded.

7.14.3.10 PMATH_API `pmath_bool_t` `pmath_file_set_binbuffer` (`pmath_t file`, `size_t size`)

Set a binary file's buffer size.

Parameters:

- file* A binary file. It wont be freed.
- size* The new size of the buffer in bytes.

Returns:

TRUE if the operation succeeded.

This function might clear the old buffer. So it should be called before any file read operation is done.

7.14.3.11 PMATH_API `void` `pmath_file_manipulate` (`pmath_t file`, `void(*) (void *) type`, `void(*) (void *, void *) callback`, `void * data`)

Manipulate a file's internal representation.

Parameters:

- file* A file object. It wont be freed.
- type* The *extra_destructor* that was provided to [pmath_file_create_binary\(\)](#) or [pmath_file_create_text\(\)](#).
- callback* A callback function. The first argument will be the *extra* parameter that was provided to [pmath_file_create_binary\(\)](#) or [pmath_file_create_text\(\)](#).
- data* The second parameter for *callback*.

If *file* is a valid file object and if *type* is the *extra_destructor* which \ file was created with, then and only then `callback()` will be called.

This function does not support lists of writeable files.

7.14.3.12 PMATH_API pmath_bool_t pmath_file_close (pmath_t *file*)

Closes a file.

Parameters:

file A file object. It will be freed.

Returns:

Whether file was a valid file object.

7.14.3.13 PMATH_API pmath_symbol_t pmath_file_create_binary (void * *extra*, void(*)(void *) *extra_destructor*, pmath_binary_file_api_t * *api*)

Create a binary file object.

Parameters:

extra Arbitrary extra data.

extra_destructor A function to destroy the extra data.

api The file access functions.

Returns:

A newly created binary file object. You can destroy and close it with [pmath_file_close\(\)](#) or [pmath_unref\(\)](#).

The *api* functions are never called by more than one thread at once. This is assured with a non-reentrant spinlock.

See also:

[pmath_binary_file_api_t](#)

7.14.3.14 PMATH_API pmath_symbol_t pmath_file_create_text (void * *extra*, void(*)(void *) *extra_destructor*, pmath_text_file_api_t * *api*)

Create a text file object.

Parameters:

extra Arbitrary extra data.

extra_destructor A function to destroy the extra data.

api The file access functions.

Returns:

A newly created text file object. You can destroy and close it with [pmath_file_close\(\)](#) or [pmath_unref\(\)](#).

The *api* functions are never called by more than one thread at once. This is assured with a non-reentrant spinlock.

See also:

[pmath_text_file_api_t](#)

7.14.3.15 PMATH_API `pmath_symbol_t` `pmath_file_create_text_from_binary` (`pmath_t binfile`, `const char * encoding`)

Create a text file object operating on a binary file.

Parameters:

binfile A binary file. It will be freed.

encoding A text encoding that the iconv library knows.

Returns:

A newly created text file object. You can destroy and close it with [pmath_file_close\(\)](#) or [pmath_unref\(\)](#).

7.14.3.16 PMATH_API `pmath_symbol_t` `pmath_file_create_binary_buffer` (`size_t mincapacity`)

Create a byte-stream file object.

Parameters:

mincapacity The initial size of the buffer.

Returns:

A newly created binary file object. You can destroy and close it with [pmath_file_close\(\)](#) or [pmath_unref\(\)](#).

You can write to a byte-buffer and read previously written data from it. Note that this does not support random access to the data.

7.14.3.17 PMATH_API `size_t` `pmath_file_binary_buffer_size` (`pmath_t binfile`)

Get The number of readable bytes in a binary buffer.

Parameters:

binfile A binary file created with [pmath_file_create_binary_buffer\(\)](#). It wont be freed.

Returns:

The number of readable bytes in the binary buffer or 0 on error.

7.14.3.18 PMATH_API void pmath_file_binary_buffer_manipulate (**pmath_t** *binfile*,
void(*)(**uint8_t** **readable*, **uint8_t** **writable*, **const uint8_t** **end*, **void** **closure*) *callback*,
void **closure*)

Manipulate the content of a binary buffer.

Parameters:

binfile A binary file created with [pmath_file_create_binary_buffer\(\)](#). It won't be freed.

callback The callback function that does the manipulation.

closure The fourth parameter for *callback*.

The *callback* function must not write before *readable* or after *end*. *writable* gives the current write-position, which is always between *readable* and *end*.

7.15 Object Utility Functions

Utility functions for pMath Objects and Expressions.

Typedefs

- typedef [pmath_bool_t](#) (* [pmath_stack_walker_t](#)) ([pmath_t](#) head, **void** **closure*)
A stack walker function.

Functions

- PMATH_API [pmath_bool_t](#) [pmath_is_expr_of](#) ([pmath_t](#) obj, [pmath_symbol_t](#) head)
Check if an object is an expression with a specified head.
- PMATH_API [pmath_bool_t](#) [pmath_is_expr_of_len](#) ([pmath_t](#) obj, [pmath_symbol_t](#) head, [size_t](#) length)
Check if an object is an expression with a specified head and length.
- PMATH_API [pmath_t](#) [pmath_current_head](#) (**void**)
Get the currently evaluated function.
- PMATH_API **void** [pmath_walk_stack](#) ([pmath_stack_walker_t](#) walker, **void** **closure*)
Walk up the current thread's and its parents' stack.
- PMATH_API [pmath_t](#) [pmath_session_start](#) (**void**)
Saves some global state when an interactive dialog session starts.
- PMATH_API **void** [pmath_session_end](#) ([pmath_t](#) old_state)
Restore some global state when an interactive dialog session ends.
- PMATH_API **void** [pmath_expr_t::pmath_gather_begin](#) ([pmath_t](#) pattern)
Start gathering emitted objects.

- PMATH_API `pmath_expr_t pmath_expr_t::pmath_gather_end` (void)
Finish gathering emitted objects.
- PMATH_API void `pmath_expr_t::pmath_emit` (pmath_t object, pmath_t tag)
Emit an object to be gathered by the appropriate surrounding `pmath_gather_begin()` ... `pmath_gather_end()` function pair.
- PMATH_API `pmath_t pmath_t::pmath_build_value_v` (const char *format, va_list args)
Generate a List of objects with a format string.
- PMATH_API `pmath_t pmath_t::pmath_build_value` (const char *format,...)
Generate a List of objects with a format string.
- PMATH_API `pmath_expr_t pmath_expr_t::pmath_options_extract` (pmath_expr_t expr, size_t last_nonoption)
Extract custom option values from an expression.
- PMATH_API `pmath_t pmath_expr_t::pmath_option_value` (pmath_t fn, pmath_t name, pmath_t extra)
Retrieve a option value of a given function.

7.15.1 Detailed Description

Utility functions for pMath Objects and Expressions.

Here are some utility functions that simplify access to Expressions (or pMath Objects in general), but do not really fit one of these topics.

7.15.2 Typedef Documentation

7.15.2.1 typedef pmath_bool_t(* pmath_stack_walker_t)(pmath_t head, void *closure)

A stack walker function.

The return value specifies, whether the walk on the stack go on.

7.15.3 Function Documentation

7.15.3.1 PMATH_API pmath_bool_t pmath_is_expr_of (pmath_t obj, pmath_symbol_t head)

Check if an object is an expression with a specified head.

Parameters:

obj A pMath object. It wont be freed.

head A pMath symbol. It wont be freed.

Returns:

TRUE iff *obj* is an expression with the given *head* which must be a symbol.

7.15.3.2 PMATH_API pmath_bool_t pmath_is_expr_of_len (pmath_t *obj*, pmath_symbol_t *head*, size_t *length*)

Check if an object is an expression with a specified head and length.

Parameters:

obj A pMath object. It wont be freed.

head A pMath symbol. It wont be freed.

length The requested expression length.

Returns:

TRUE iff *obj* is an expression with the given *length* and *head* which must be a symbol.

7.15.3.3 PMATH_API pmath_t pmath_current_head (void)

Get the currently evaluated function.

Returns:

The head of the expression that is currently evaluated (in the calling thread). You have to destroy it.

7.15.3.4 PMATH_API void pmath_walk_stack (pmath_stack_walker_t *walker*, void * *closure*)

Walk up the current thread's and its parents' stack.

Parameters:

walker A callback function.

closure A pointer that will be provided to *walker* as the second argument.

7.15.3.5 PMATH_API pmath_t pmath_session_start (void)

Saves some global state when an interactive dialog session starts.

Returns:

A pMath object to be given to [pmath_session_end\(\)](#)

This function should be used by a frontend when implementing the `Dialog()` function.

7.15.3.6 PMATH_API void `pmath_session_end` (`pmath_t old_state`)

Restore some global state when an interactive dialog session ends.

Parameters:

old_state The object returned by [pmath_session_start\(\)](#). It will be freed.

This function should be used by a frontend when implementing the `Dialog()` function.

7.15.3.7 PMATH_API void `pmath_gather_begin` (`pmath_t pattern`) [related, inherited]

Start gathering emitted objects.

Parameters:

pattern A pattern that is used to determine which emitted objects should be gathered (testing the emit-tag, not the object itself). It will be freed.

Use [pmath_gather_end\(\)](#) to finish gathering. Calls to [pmath_gather_begin\(\)](#) ... [pmath_gather_end\(\)](#) can be nested.

The emit-and-gather mechanism is useful when you want to create a list but do not know its final length in advance.

See also:

[pmath_emit](#)

7.15.3.8 PMATH_API `pmath_expr_t` `pmath_gather_end` (`void`) [related, inherited]

Finish gathering emitted objects.

Returns:

A list of all emitted objects since the last [pmath_gather_begin\(\)](#) whose emit-tag matched the `pattern` parameter given to that [pmath_gather_begin\(\)](#). You must free it.

See also:

[pmath_emit](#)

7.15.3.9 PMATH_API void `pmath_emit` (`pmath_t object`, `pmath_t tag`) [related, inherited]

Emit an object to be gathered by the appropriate surrounding [pmath_gather_begin\(\)](#) ... [pmath_gather_end\(\)](#) function pair.

Parameters:

object The object to be emitted, it will be freed.

tag A tag object. The surrounding Gather() with a pattern, that matches *tag* will collect the object.
tag will be freed.

See also:

[pmath_gather_begin](#)

[pmath_gather_end](#)

7.15.3.10 PMATH_API *pmath_t* *pmath_build_value_v* (const char **format*, va_list *args*) [related, inherited]

Generate a List of objects with a format string.

Parameters:

format A string that specifies the tuple's item's type.

args A va_list - variable argument list.

This function interface is only given if stdarg.h was included before.

See also:

[pmath_build_value](#)

7.15.3.11 PMATH_API *pmath_t* *pmath_build_value* (const char **format*, ...) [related, inherited]

Generate a List of objects with a format string.

Parameters:

format A string that specifies the tuple's item's type. See below.

... The tuple/list items

The format string characters specify the item's type:

- *b* [int] converts a C int to True or False
- *i* [int]
- *l* [long int]
- *k* [long long int]
- *n* [ssize_t]
- *I* [unsigned int]

- `L` [unsigned long int]
- `K` [unsigned long long int]
- `N` [size_t]
- `f` [double] NaN's and Infinity are converted to Indeterminate and +/-Infinity
- `o` [[pmath_t](#)] A pMath Object, the reference is stolen
- `c` [int] convert a C int representing a (unicode) character to a string of length 1.
- `s` [char*] converts a zero-terminated C string to a pMath string using Latin-1 encoding.
- `s#` [char*,int] takes a char buffer and a length to build a pMath string of that length using Latin-1 encoding.
- `z` [char*] a zero-terminated C string and converts it to a symbol using [pmath_symbol_find\(\)](#).
- `u` [char*] converts a zero-terminated C string to a pMath string using UTF-8 encoding.
- `u#` [char*,int] takes a char buffer and a length to build a pMath string of that length using UTF-8 encoding.
- `U` [uint16_t*] converts a zero-terminated double-byte C string to a pMath string using UTF-16 encoding. This is generally useful only where `sizeof(uint16_t) == sizeof(wchar_t)`, e.g. Windows but not Linux.
- `U#` [uint16_t*,int] takes a character buffer and a length to build a pMath string of that length using UTF-16 encoding. This is generally useful only on platforms with `sizeof(uint16_t) == sizeof(wchar_t)`, e.g. Windows but not Linux.
- `Ctt` [matching the 2 t's] build a complex value
- `Qtt` [matching the 2 t's] build a rational value from two integers.
- `(items)` [matching items] constructs a sublist of items.

Note:

When the format string denotes only one object, this object will be returned alone. So for a [pmath_t](#) `x`, `pmath_build_value("o", x) == x`.

If you want to return a list in any case, use "(...)": "i" gives an integer, "ii" and "(ii)" a list of two integers and "(i)" a list of one integer.

7.15.3.12 PMATH_API `pmath_expr_t` `pmath_options_extract` (`pmath_expr_t` *expr*, `size_t` *last_option*) [*related, inherited*]

Extract custom option values from an expression.

Parameters:

expr The expression that may custom option values. It wont be freed.

last_nonoption The index of the last argument that is not a option rule.

Returns:

A list of all given option values or NULL on error. You must destroy it.

Imagine, `expr = 'f(a,b,A->1,B->2)'` and `last_nonoption` is 2, then the result value is a list '{A->1, B->2}'. You can use this return value as the `extra` parameter in `pmath_option_value()`.

When `last_nonoption` was 1, a message would be generated (b is no rule ...) and the return value is NULL. In that case, the calling function should have no further effects and return.

7.15.3.13 PMATH_API `pmath_t pmath_option_value (pmath_t fn, pmath_t name, pmath_t extra)` [related, inherited]

Retrieve a option value of a given function.

Parameters:

fn The function for which the requested option value is defined. It wont be freed. If it is NULL, the current head (see `pmath_current_head`) will be used.

name The name of the option value (in general, a symbol). It wont be freed.

extra A list of extra option rules or PMATH_UNDEFINED. It wont be freed. If it is not PMATH_UNDEFINED, it must be a rule ('a->b', 'a:>b') or a list of rules.

Returns:

The requested option value.

7.16 Memory Management

Memory management for pMath.

Functions

- PMATH_API void * `pmath_mem_alloc` (size_t size)
Allocate some amount of memory.
- PMATH_API void * `pmath_mem_realloc` (void *p, size_t new_size)
Change the size of a memory-chunk.
- PMATH_API void * `pmath_mem_realloc_no_failfree` (void *p, size_t new_size)
Change the size of a memory-chunk.
- PMATH_API void `pmath_mem_free` (void *p)
Free a memory-chunk.
- PMATH_API void `pmath_mem_usage` (size_t *current, size_t *max)
Get memory usage information.

7.16.1 Detailed Description

Memory management for pMath.

These functions may return NULL. In this case, the current evaluation will abort and used cache will be freed to safe memory (a simple garbage collector for pMath symbols and numbers, which are not freed automatically, starts).

See also:

PMATH_INIT_WINDOWS_DONT_USE_LOW_FRAGMENTATION_HEAP

7.16.2 Function Documentation

7.16.2.1 PMATH_API void* pmath_mem_alloc (size_t size)

Allocate some amount of memory.

Parameters:

size The number of bytes to be allocated.

Returns:

A pointer to a block of mamory of at least size bytes or NULL.

You must free the result with [pmath_mem_free\(\)](#) or indirectly via [pmath_mem_realloc\(\)](#).

7.16.2.2 PMATH_API void* pmath_mem_realloc (void *p, size_t new_size)

Change the size of a memory-chunk.

Parameters:

p NULL or a pointer to a block of old_size bytes allocated with [pmath_mem_alloc\(\)](#) or [pmath_mem_realloc\(\)](#).

new_size The requested new size.

Returns:

A pointer to a block of at least new_size bytes or NULL.

If there is not enough memory available or if new_size == 0, NULL is returned. Otherwise, the result points to a block of new_size bytes, whose first min(old_size,new_size) bytes are copied from the old p. The rest is initialized with 0.

The old pointer p will _always_ be freed. even, if the result is NULL because there is not enough memory.

You must free the result with [pmath_mem_free\(\)](#) or indirectly via [pmath_mem_realloc\(\)](#).

7.16.2.3 PMATH_API void* pmath_mem_realloc_no_failfree (void * *p*, size_t *new_size*)

Change the size of a memory-chunk.

Parameters:

- p* NULL or a pointer to a block of *old_size* bytes allocated with [pmath_mem_alloc\(\)](#) or [pmath_mem_realloc\(\)](#).
- new_size* The requested new size.

Returns:

A pointer to a block of at least *new_size* bytes or NULL.

If there is enough memory, this acts like [pmath_mem_realloc\(\)](#). Otherwise, *p* is *not* freed and NULL is returned.

7.16.2.4 PMATH_API void pmath_mem_free (void * *p*)

Free a memory-chunk.

Parameters:

- p* NULL or a pointer to a block of *old_size* bytes allocated with [pmath_mem_alloc\(\)](#) or [pmath_mem_realloc\(\)](#).

7.16.2.5 PMATH_API void pmath_mem_usage (size_t * *current*, size_t * *max*)

Get memory usage information.

Parameters:

- current* Here goes the number of currently allocated bytes.
- max* here goes the maximum number of allocated bytes until now.

7.17 Messages

Error handling and informing the user.

Functions

- PMATH_API void [pmath_message](#) ([pmath_symbol_t](#) symbol, const char *tag, size_t argcount,...)
Print a message with pMath object arguments.
- PMATH_API void [pmath_message_argxxx](#) (size_t given, size_t min, size_t max)
Generate a General::arg message (invalid argument count).*

- PMATH_API `pmath_string_t pmath_message_find_text (pmath_t name)`
Find a message's text.
- PMATH_API void `pmath_message_syntax_error (pmath_string_t code, int position, pmath_string_t filename, int lines_before_code)`
Print a syntax warning or error message.

7.17.1 Detailed Description

Error handling and informing the user.

When you encounter an error such as wrong argument usage in pMath functions, you just print out a message and return the handled expression unevaluated. You do *not* call `pmath_abort_please()`.

Example: The built in Power function invokes the `Power::indet` in case of 0^0 .

If you notice that a memory allocation failed, do nothing at all (even do not try to print a message). pMath automatically calls `pmath_abort_please()` on out-of-memory and thus no message would be shown.

Messages are similar to Mathematicas approach. On the language level, you enter `'Message(symbol::tag, ...)` to print a message with optional inserted values `'...'`. You can use Backquotes to refer to given values.

You can use all messages of the symbol General with every other symbol.

7.17.2 Function Documentation

7.17.2.1 PMATH_API void pmath_message (pmath_symbol_t symbol, const char * tag, size_t argcount, ...)

Print a message with pMath object arguments.

Parameters:

symbol The symbol, that defines the message. It wont be freed. NULL will be treated as `pmath_current_head()`. This is useful, because `pmath_current_head()` returns a reference, but `pmath_message()` would not free it.

tag The message's tag as a zero-terminated C string.

argcount The number of following arguments.

... Exactly *argcount* pMath objects. They all will be freed.

Note:

If `symbol==NULL` and `pmath_current_head()` is an expression `f()`, the function acts as if `pmath_current_head()` was `f`.

All the symbols and expressions in `...` will be embedded in `HoldForm(...)`, because `Message()` would evaluate them. If you want one of the values to be evaluated, do it manually.

7.17.2.2 PMATH_API void pmath_message_argxxx (size_t *given*, size_t *min*, size_t *max*)

Generate a General::arg* message (invalid argument count).

Parameters:

- given* The given number of arguments.
- min* The minimum expected number of arguments.
- max* The maximum expected number of arguments.

7.17.2.3 PMATH_API pmath_string_t pmath_message_find_text (pmath_t *name*)

Find a message's text.

Parameters:

- name* An expression of the form symbol::name (that is MessageName(symbol, "name")). It will be freed.

Returns:

The message's content or NULL if nothing was found or the [magic value PMATH_UNDEFINED](#), if *name* does not have the expected form.

This function can be used in front-ends that overwrite the built-in Message function.

7.17.2.4 PMATH_API void pmath_message_syntax_error (pmath_string_t *code*, int *position*, pmath_string_t *filename*, int *lines_before_code*)

Print a syntax warning or error message.

Parameters:

- code* The code. A pMath string. It wont be freed.
- position* The position of the syntax error in the code.
- filename* The file from where the input came or NULL to omit it. It will be freed.
- lines_before_code* The number of lines in the input file before *code* was read. This is ignored if *filename* is NULL.

This function produces a Syntax::bgn, Syntax::bgf, Syntax::nxt, Syntax::nxtf, Syntax::more, Syntax::moref, Syntax::newl or Syntax::newlf message, depending on where the syntax error is in the *code* and whether *filename* is not NULL. It can be used to report errors/warnings from [pmath_spans_from_string\(\)](#).

7.18 Threadsafe Stacks

Fast threadsafe stacks in pMath.

Data Structures

- class `pmath_stack_t`
The type of pMath's threadsafe stacks.

Functions

- PMATH_API `pmath_stack_t pmath_stack_new` (void)
Create an empty stack.
- PMATH_API void `pmath_stack_free` (`pmath_stack_t` stack)
Destroy a stack.
- PMATH_API void `pmath_stack_push` (`pmath_stack_t` stack, void *item)
Push an item onto a stack.
- PMATH_API void * `pmath_stack_pop` (`pmath_stack_t` stack)
Pop an item from a stack.

7.18.1 Detailed Description

Fast threadsafe stacks in pMath.

`pmath_stack_t` is a stack abstraction that provides threadsafe push and pop operations. You can push and pop any structure whose first element is a pointer (which you must not touch).

If your CPU supports it, very fast lockfree operations are used for push and pop.

References

- Fober, Orlarey, Letz: "Lock-Free Techniques for Concurrent Access to Shared Objects" (http://pagesperso-orange.fr/gmem/evenements/jim2002/articles/L17_Fober.pdf)

7.18.2 Function Documentation

7.18.2.1 PMATH_API `pmath_stack_t pmath_stack_new` (void)

Create an empty stack.

Returns:

A new stack or NULL.

Note that you cannot push anything onto a NULL stack, so check the result. Free the result with `pmath_stack_free()`.

7.18.2.2 PMATH_API void pmath_stack_free (pmath_stack_t stack)

Destroy a stack.

Parameters:

stack A stack previously created with [pmath_stack_new\(\)](#). May be NULL.

You must manually pop and free all items on the stack before calling this function, because those items would not be freed automatically.

7.18.2.3 PMATH_API void pmath_stack_push (pmath_stack_t stack, void * item)

Push an item onto a stack.

Parameters:

stack The stack to where the item should be pushed. Must not be NULL.

item The item to be pushed. It must point to a structure whose first element is a pointer. Must not be NULL.

7.18.2.4 PMATH_API void* pmath_stack_pop (pmath_stack_t stack)

Pop an item from a stack.

Parameters:

stack The stack to pop an item from. Must not be NULL.

Returns:

The top of stack or NULL if it is empty.

7.19 Front-ends

Functions for use front-ends.

Functions

- PMATH_API [pmath_bool_t pmath_continue_after_abort](#) (void)
Requests pMath to stop aborting the current evaluation.
- PMATH_API [pmath_t pmath_session_execute](#) (pmath_t input, [pmath_bool_t](#) *aborted)
Execute an expression and change \$History and \$Line appropriately.
- PMATH_API [pmath_bool_t pmath_init](#) (void)

Initialize the pMath CAS library.

- PMATH_API void [pmath_done](#) (void)

Free all resources used by the pMath CAS library and unload all modules.

7.19.1 Detailed Description

Functions for use front-ends.

A front-end to pMath is an executable, that initializes and finalizes the library and handles User input and output or otherwise invokes expression evaluation with the library. That is, what pMath does: parse and evaluate pMath code.

7.19.2 Function Documentation

7.19.2.1 PMATH_API [pmath_bool_t](#) [pmath_continue_after_abort](#) (void)

Requests pMath to stop aborting the current evaluation.

Returns:

Whether the global aborting-flag was set (by [pmath_abort_please\(\)](#))

This is for use in front-ends to allow the user to continue working after he aborted an evaluation.

Any uncought exception will be deleted silently.

This function also clears the \$MessageCount cache.

See also:

[pmath_abort_please\(\)](#)

7.19.2.2 PMATH_API [pmath_t](#) [pmath_session_execute](#) ([pmath_t](#) *input*, [pmath_bool_t](#) * *aborted*)

Execute an expression and change \$History and \$Line appropriately.

Parameters:

input The input expression. It will be freed.

aborted Optional address of a flag that will be set iff the evaluation was aborted by [pmath_abort_please\(\)](#)

Returns:

The return value is the same as [pmath_evaluate\(input\)](#)

This function also calls [pmath_collect_temporary_symbols](#) before evaluation.

7.19.2.3 PMATH_API pmath_bool_t pmath_init (void)

Initialize the pMath CAS library.

Returns:

TRUE, if the initialization was successful, FALSE otherwise.

Any thread must call [pmath_init\(\)](#) before using any other pMath function (exception: [Atomic Operations](#)). If the initialization fails, the thread should stop. Otherwise, [pmath_done\(\)](#) must be called before the thread ends.

7.19.2.4 PMATH_API void pmath_done (void)

Free all resources used by the pMath CAS library and unload all modules.

See also:

[pmath_init](#)

8 Data Structure Documentation

8.1 pmath::Expr Class Reference

A wrapper for [pmath_t](#) and derived types.

Inherited by [pmath::String](#).

Public Member Functions

- [Expr](#) ([pmath_t](#) obj=0) throw ()
Construct from a [pmath_t](#), stealing the reference.
- bool [instance_of](#) ([pmath_type_t](#) type) const throw ()
Check for underlying pMath C API type.
- unsigned int [hash](#) () const throw ()
Get a hash value.
- bool [operator==](#) (const [Expr](#) &other) const throw ()
check for identity. The pMath == operator.
- bool [operator!=](#) (const [Expr](#) &other) const throw ()
check for identity. The pMath != operator.
- [pmath_t](#) [release](#) () throw ()
Return the [pmath_t](#) and discard it. Caller must [pmath_unref\(\)](#) it.

- const [pmath_t](#) [get](#) () const throw ()
Get the [pmath_t](#). Reference is held by the [Expr](#) object.
- bool [is_valid](#) () const throw ()
Check for null pointer.
- size_t [expr_length](#) () const throw ()
Length of the expression or 0 on error.
- [Expr operator\[\]](#) (size_t *i*) const throw ()
**i*-th argument of the expression.*
- double [to_double](#) (double *def*=0.0) const throw ()
Convert to a double.
- [String to_string](#) ([pmath_write_options_t](#) *options*=0) const throw ()
Convert to a string.

8.1.1 Detailed Description

A wrapper for [pmath_t](#) and derived types.

This class wraps a single [pmath_t](#), so its size is sizeof(void*).

8.1.2 Member Function Documentation

8.1.2.1 Expr pmath::Expr::operator[] (size_t *i*) const throw () [inline]

i-th argument of the expression.

Parameters:

i Index. May be > length().

Returns:

The *i*-th argument if the object is a [pmath_expr_t](#). `expr[0]` is the head, `expr[1]` the first argument and `expr[length()]` the last argument.

8.1.2.2 double pmath::Expr::to_double (double *def* = 0.0) const throw () [inline]

Convert to a double.

Parameters:

def Optional default value.

Returns:

the double value if the object is a numeric object and *def* otherwise.

8.1.2.3 String pmath::Expr::to_string (pmath_write_options_t options = 0) const throw ()
[inline]

Convert to a string.

Parameters:

options Optional output options.

Returns:

The [String](#) representation.

The documentation for this class was generated from the following file:

- pmath-cpp.h

8.2 pmath::Gather Class Reference

Utility class for emitting and gathering expressions/building lists Gathering begins with the construction of the object and ends with a call to [end\(\)](#) or the object destruction.

Public Member Functions

- [Expr end \(\)](#)
end gathering.

Static Public Member Functions

- static void [Emit \(Expr e\)](#)
emit a value to be gathered.

8.2.1 Detailed Description

Utility class for emitting and gathering expressions/building lists Gathering begins with the construction of the object and ends with a call to [end\(\)](#) or the object destruction.

Note:

Gathering multiple lists at once is not supported!

The documentation for this class was generated from the following file:

- pmath-cpp.h

8.3 pmath_binary_file_api_t Class Reference

Access functions for binary files.

Data Fields

- [size_t struct_size](#)
The structure size. Always initialize this with `sizeof(pmath_binary_file_api_t)`.
- [pmath_files_status_t\(* status_function\)](#)(void *extra)
A function to get the current file status This can be NULL if read_function is also NULL.
- [size_t\(* read_function\)](#)(void *extra, void *buffer, size_t buffer_size)
An optional callback function for reading bytes.
- [size_t\(* write_function\)](#)(void *extra, const void *buffer, size_t buffer_size)
An optional callback function for writing bytes.
- [void\(* flush_function\)](#)(void *extra)
An optional callback function for flushing an output buffer.

8.3.1 Detailed Description

Access functions for binary files.

See also:

[pmath_file_create_binary](#)

The documentation for this class was generated from the following file:

- pmath-util/files.h

8.4 pmath_cstr_writer_info_t Struct Reference

Additional information for [pmath_utf8_writer\(\)](#) or [pmath_native_writer\(\)](#).

8.4.1 Detailed Description

Additional information for [pmath_utf8_writer\(\)](#) or [pmath_native_writer\(\)](#).

The documentation for this struct was generated from the following file:

- pmath-core/strings.h

8.5 `pmath_custom_t` Class Reference

The Custom Object class.

Inherits [pmath_t](#).

Inherited by [pmath_messages_t](#).

Public Member Functions

- PMATH_API [pmath_custom_t](#) [pmath_custom_new](#) (void *data, [pmath_callback_t](#) destructor)
Create a custom object.
- PMATH_API void * [pmath_custom_get_data](#) ([pmath_custom_t](#) custom)
Get a custom object's data member.
- PMATH_API [pmath_bool_t](#) [pmath_custom_has_destructor](#) ([pmath_custom_t](#) custom, [pmath_callback_t](#) dtor)
Get a custom object's data destructor.

8.5.1 Detailed Description

The Custom Object class.

Since it is derived from [pmath_t](#), you can provide it to any function that accepts a [pmath_t](#).

The documentation for this class was generated from the following file:

- `pmath-core/custom.h`

8.6 `pmath_expr_t` Class Reference

The Expression class.

Inherits [pmath_t](#).

Public Member Functions

- PMATH_API [pmath_expr_t](#) [pmath_expr_new](#) ([pmath_t](#) head, [size_t](#) length)
Create a new expression.
- PMATH_API [pmath_expr_t](#) [pmath_expr_new_extended](#) ([pmath_t](#) head, [size_t](#) length,...)
Create a new expression with all items given.
- PMATH_API [pmath_expr_t](#) [pmath_expr_resize](#) ([pmath_expr_t](#) expr, [size_t](#) new_length)
Resize an expression.
- PMATH_API [pmath_expr_t](#) [pmath_expr_append](#) ([pmath_expr_t](#) expr, [size_t](#) count,...)
Append some items to an expression.
- PMATH_API [size_t](#) [pmath_expr_length](#) ([pmath_expr_t](#) expr)

Get an expression's length.

- PMATH_API `pmath_t pmath_expr_get_item` (`pmath_expr_t` expr, `size_t` index)

Get an item from an expression.

- PMATH_API `pmath_expr_t pmath_expr_get_item_range` (`pmath_expr_t` expr, `size_t` start, `size_t` length)

Get multiple items from an expression.

- PMATH_API `pmath_expr_t pmath_expr_set_item` (`pmath_expr_t` expr, `size_t` index, `pmath_t` item)

Set an item in an expression.

- PMATH_API `pmath_expr_t pmath_expr_remove_all` (`pmath_expr_t` expr, `pmath_t` rem)

Remove all occurrences of an object from an expression.

- PMATH_API `pmath_expr_t pmath_expr_sort` (`pmath_expr_t` expr)

Sort an expression.

- PMATH_API `pmath_expr_t pmath_expr_flatten` (`pmath_expr_t` expr, `pmath_t` head, `size_t` depth)

Flatten an expression.

Related Functions

(Note that these are not member functions.)

- PMATH_API `pmath_t pmath_evaluate_expression` (`pmath_expr_t` expr, `pmath_bool_t` apply_rules)

Partly evaluate an expression.

- PMATH_API void `pmath_gather_begin` (`pmath_t` pattern)

Start gathering emitted objects.

- PMATH_API `pmath_expr_t pmath_gather_end` (void)

Finish gathering emitted objects.

- PMATH_API void `pmath_emit` (`pmath_t` object, `pmath_t` tag)

Emit an object to be gathered by the appropriate surrounding `pmath_gather_begin()` ... `pmath_gather_end()` function pair.

- PMATH_API `pmath_expr_t pmath_options_extract` (`pmath_expr_t` expr, `size_t` last_nonoption)

Extract custom option values from an expression.

- PMATH_API `pmath_t pmath_option_value` (`pmath_t` fn, `pmath_t` name, `pmath_t` extra)

Retrieve a option value of a given function.

8.6.1 Detailed Description

The Expression class.

Because [pmath_expr_t](#) is derived from [pmath_t](#), you can use expressions wherever a [pmath_t](#) is accepted. E.g. you calculate an expression's hash value with [pmath_hash\(\)](#).

The `pmath_type_t` of strings is `PMATH_TYPE_EXPRESSION`.

Expressions are arranged as array of objects. At index 0 is allways the head (function name). All arguments are at indices 1 to the length of the expression (including).

At the pMath language level, any exprssion can be entered in the form `'f(a,b,c,...)'` or `'a.f(b,c,...)'`. For expressions with only one argument, `'a.f'` can be used instead of `'a.f()'`.

8.6.2 Friends And Related Function Documentation

8.6.2.1 PMATH_API pmath_t pmath_evaluate_expression (pmath_expr_t *expr*, pmath_bool_t *apply_rules*) [related]

Partly evaluate an expression.

Parameters:

- expr* A pMath expression. It will be freed. Do not use it afterwards.
- apply_rules* Whether to apply custom rules the the whole expression or not.

Returns:

A new object produced by pMath's and user defined evaluation rules.

This function prepares an expression for evaluation (evaluates its items, ...).

Unlike [pmath_evaluate\(\)](#), it does not evaluate its result. In fact, [pmath_evaluate\(\)](#) is basically a loop that calls [pmath_evaluate_expression\(\)](#) until the result does not change any more.

The documentation for this class was generated from the following files:

- `pmath-core/expressions.h`
- `pmath-util/evaluation.h`
- `pmath-util/helpers.h`

8.7 pmath_float_t Class Reference

The Floating Point Number class.

Inherits [pmath_number_t](#).

Public Member Functions

- PMATH_API [pmath_number_t](#) [pmath_float_new_str](#) (const char *str, int base, pmath_precision_control_t precision_control, double base_precision_accuracy)
Create a floating point number from a string.

- PMATH_API `pmath_float_t pmath_float_new_d` (double dbl)
Create a machine-precision floating point number from a double.

8.7.1 Detailed Description

The Floating Point Number class.

Because `pmath_float_t` is derived from `pmath_number_t`, you can use pMath integers wherever a `pmath_number_t` is accepted.

The `pmath_type_t` of floats is `PMATH_TYPE_FLOAT`.

There are two hidden implementations of floating point numbers in pMath. One operates on double values. The other uses MPFR for multiple precision numbers and provides automatic precision tracking.

The documentation for this class was generated from the following file:

- `pmath-core/numbers.h`

8.8 `pmath_integer_t` Class Reference

The Integer class.

Inherits `pmath_rational_t`.

Public Member Functions

- PMATH_API `pmath_integer_t pmath_integer_new_si` (signed long int si)
Create an integer object from a signed long.
- PMATH_API `pmath_integer_t pmath_integer_new_ui` (unsigned long int ui)
Create an integer object from an unsigned long.
- PMATH_API `pmath_integer_t pmath_integer_new_size` (size_t size)
Create an integer object from an size_t.
- PMATH_API `pmath_integer_t pmath_integer_new_data` (size_t count, int order, int size, int endian, size_t nails, const void *data)
Create an integer object from a data buffer.
- PMATH_API `pmath_integer_t pmath_integer_new_str` (const char *str, int base)
Create an integer object from a C String.
- PMATH_API `pmath_bool_t pmath_integer_fits_si` (`pmath_integer_t` integer)
Find out whether a pMath integer fits into a signed long int.
- PMATH_API `pmath_bool_t pmath_integer_fits_ui` (`pmath_integer_t` integer)
Find out whether a pMath integer fits into a unsigned long int.
- PMATH_API signed long int `pmath_integer_get_si` (`pmath_integer_t` integer)

Convert a pMath integer to a signed long int.

- PMATH_API unsigned long int [pmath_integer_get_ui](#) ([pmath_integer_t](#) integer)

Convert a pMath integer to a unsigned long int.

8.8.1 Detailed Description

The Integer class.

Because [pmath_integer_t](#) is derived from [pmath_rational_t](#), you can use pMath integers wherever a [pmath_rational_t](#) is accepted.

The [pmath_type_t](#) of integers is PMATH_TYPE_INTEGER.

The documentation for this class was generated from the following file:

- [pmath-core/numbers.h](#)

8.9 pmath_messages_t Class Reference

A message queue for interthread communication.

Inherits [pmath_custom_t](#).

Related Functions

(Note that these are not member functions.)

- PMATH_API [pmath_bool_t](#) [pmath_is_message_queue](#) ([pmath_t](#) obj)
Test if an object is a message queue.
- PMATH_API [pmath_messages_t](#) [pmath_thread_get_queue](#) (void)
Get the current thread's message queue.
- PMATH_API void [pmath_thread_sleep](#) (void)
Send the current thread to sleep.
- PMATH_API void [pmath_thread_wakeup](#) ([pmath_messages_t](#) mq)
Wake up another thread.
- PMATH_API void [pmath_thread_send](#) ([pmath_messages_t](#) mq, [pmath_t](#) msg)
Asynchronously send a message to another thread.
- PMATH_API [pmath_t](#) [pmath_thread_send_wait](#) ([pmath_messages_t](#) mq, [pmath_t](#) msg, double timeout_seconds)
Send a message to another thread and wait for the answer.
- PMATH_API void [pmath_thread_send_delayed](#) ([pmath_messages_t](#) mq, [pmath_t](#) msg, double seconds)
Asynchronously send a message to a thread sometime in the future.

8.9.1 Detailed Description

A message queue for interthread communication.

The documentation for this class was generated from the following file:

- `pmath-util/concurrency/threadmsg.h`

8.10 `pmath_number_t` Class Reference

The abstract Number class.

Inherits [pmath_t](#).

Inherited by [pmath_float_t](#), and [pmath_rational_t](#).

Public Member Functions

- PMATH_API double [pmath_number_get_d](#) ([pmath_number_t](#) number)
Convert a pMath number to a double.
- PMATH_API int [pmath_number_sign](#) ([pmath_number_t](#) num)
Get a number's sign.
- PMATH_API [pmath_number_t](#) [pmath_number_neg](#) ([pmath_number_t](#) num)
Get a number's negative.

8.10.1 Detailed Description

The abstract Number class.

Because [pmath_integer_t](#) is derived from [pmath_number_t](#), you can use pMath integers wherever a [pmath_number_t](#) is accepted.

The [pmath_type_t](#) of numbers is `PMATH_TYPE_NUMBER`.

See also:

[Objects - the Base of pMath](#)

The documentation for this class was generated from the following file:

- `pmath-core/numbers.h`

8.11 `pmath_quotient_t` Class Reference

The Quotient class.

Inherits [pmath_rational_t](#).

8.11.1 Detailed Description

The Quotient class.

Because `pmath_quotient_t` is derived from `pmath_rational_t`, you can use pMath integers wherever a `pmath_rational_t` is accepted.

The `pmath_type_t` of quotients is `PMATH_TYPE_QUOTIENT`. However, you rarely test on this but on `PMATH_TYPE_RATIONAL`, because quotients whose denominator divides the numerator without a remainder, are converted to `pmath_integer_t` automatically.

The documentation for this class was generated from the following file:

- `pmath-core/numbers.h`

8.12 `pmath_rational_t` Class Reference

The abstract Rational Number class.

Inherits `pmath_number_t`.

Inherited by `pmath_integer_t`, and `pmath_quotient_t`.

Public Member Functions

- `PMATH_API pmath_rational_t pmath_rational_new` (`pmath_integer_t` numerator, `pmath_integer_t` denominator)
Create a rational number.
- `PMATH_API pmath_integer_t pmath_rational_numerator` (`pmath_rational_t` rational)
Get the numerator of a rational number.
- `PMATH_API pmath_integer_t pmath_rational_denominator` (`pmath_rational_t` rational)
Get the denominator of a rational number.

8.12.1 Detailed Description

The abstract Rational Number class.

Because `pmath_rational_t` is derived from `pmath_number_t`, you can use pMath integers wherever a `pmath_number_t` is accepted.

The `pmath_type_t` of rational numbers is `PMATH_TYPE_RATIONAL`.

The documentation for this class was generated from the following file:

- `pmath-core/numbers.h`

8.13 `pmath_span_array_t` Class Reference

Internal flat representaion of spans.

Public Member Functions

- PMATH_API void [pmath_span_array_free](#) (`pmath_span_array_t` *spans)
Destroy a span-array and all its spans.
- PMATH_API int [pmath_span_array_length](#) (`pmath_span_array_t` *spans)
Get a span-array's length.
- PMATH_API `pmath_bool_t` [pmath_span_array_is_token_end](#) (`pmath_span_array_t` *spans, int pos)
Test the token-end-flag at an index.
- PMATH_API `pmath_bool_t` [pmath_span_array_is_operator_start](#) (`pmath_span_array_t` *spans, int pos)
Test the operator-start-flag at an index.
- PMATH_API `pmath_span_t` * [pmath_span_at](#) (`pmath_span_array_t` *spans, int pos)
Get a span starting at an index.

8.13.1 Detailed Description

Internal flat representaion of spans.

The boxform of `aa*bbb+cc^dd*ee` is `{{"aa", "*", "bbb"}, "+", {"cc", "^", {"-", "dd"}}, "*", "ee"}}`

But those lists are not practicable for front-ends, so pMath provides a flat representation called *span-array*. It is an array of spans and flags (see [pmath_span_at\(\)](#), [pmath_span_array_is_token_end\(\)](#), [pmath_span_array_is_operator_start\(\)](#)).

The above code would be scanned to the following span array (the text itself is not stored):

```

operand start: aa*bbb+cc^dd*ee
token end:    x  x  x  xx x
              x  xx xxx xx x
spans <       /      \      /
              \      /      \
index:        0      5      10     15
```

So at index 0 is a span which ends with index 15. It has a next span (a shorter span that starts at the same position) which ends with index 5.

Another span is at index 7. It ends with index 15 and has a next span which ends with index 12.

The last span is at index 10 and also ends with index 12.

No two spans can cross-overlap so there is a definite hierachy. You create such a span-array with [pmath_spans_from_string\(\)](#) and destroy it with [pmath_span_array_free\(\)](#).

The documentation for this class was generated from the following file:

- `pmath-language/scanner.h`

8.14 `pmath_span_t` Class Reference

Represents a span in a [span-array](#).

Public Member Functions

- PMATH_API [pmath_span_t](#) * [pmath_span_next](#) ([pmath_span_t](#) *span)
Get the next-shorter span starting at the same position.
- PMATH_API int [pmath_span_end](#) ([pmath_span_t](#) *span)
Get end of a span.

8.14.1 Detailed Description

Represents a span in a [span-array](#).

The documentation for this class was generated from the following file:

- `pmath-language/scanner.h`

8.15 `pmath_stack_t` Class Reference

The type of pMath's threadsafe stacks.

8.15.1 Detailed Description

The type of pMath's threadsafe stacks.

You can create it with [pmath_stack_new\(\)](#) and must destroy it with [pmath_stack_free\(\)](#).

The documentation for this class was generated from the following file:

- `pmath-util/stacks.h`

8.16 `pmath_string_t` Class Reference

The string class.

Inherits [pmath_t](#).

Public Member Functions

- PMATH_API [pmath_string_t](#) [pmath_string_new](#) (int capacity)
Create an empty pMath String.
- PMATH_API [pmath_string_t](#) [pmath_string_insert LATIN1](#) ([pmath_string_t](#) str, int inspos, const char *ins, int inslen)
Insert an Latin-1 encoded buffer into a pMath String.

- PMATH_API `pmath_string_t pmath_string_from_utf8` (const char *str, int len)
Convert an UTF-8 encoded buffer to a pMath String.
- PMATH_API char * `pmath_string_to_utf8` (pmath_string_t str, int *result_len)
Convert a pMath string to a zero-terminated UTF-8 string.
- PMATH_API `pmath_string_t pmath_string_from_native` (const char *str, int len)
Convert a string buffer in the current console character encoding to a pMath String.
- PMATH_API char * `pmath_string_to_native` (pmath_string_t str, int *result_len)
Convert a pMath string to a string in the current console character encoding.
- `PMATH_C_STRING`(cstr)
Short form to convert a C String to a pMath String.
- PMATH_API `pmath_string_t pmath_string_insert_codepage` (pmath_string_t str, int inspos, const char *ins, int inslen, const uint16_t *cp)
Insert a byte string into a pMath string using a translation array.
- PMATH_API `pmath_string_t pmath_string_insert_ucs2` (pmath_string_t str, int inspos, const uint16_t *ins, int inslen)
Insert a UCS-2 buffer into a pMath String.
- PMATH_API `pmath_string_t pmath_string_insert` (pmath_string_t str, int inspos, pmath_string_t ins)
Insert one pMath String into another pMath String.
- PMATH_API `pmath_string_t pmath_string_concat` (pmath_string_t prefix, pmath_string_t postfix)
Concatenate two pMath Strings.
- PMATH_API `pmath_string_t pmath_string_part` (pmath_string_t string, int start, int length)
Extract a substring of a pMath String.
- PMATH_API const uint16_t * `pmath_string_buffer` (pmath_string_t string)
Get a string's buffer for reading.
- PMATH_API int `pmath_string_length` (pmath_string_t string)
Get a string's length.
- PMATH_API `pmath_bool_t pmath_string_equals_latin1` (pmath_string_t string, const char *latin1)
Compare a pMth sting with a C string.

Related Functions

(Note that these are not member functions.)

- PMATH_API `pmath_t pmath_string_expand_boxes` (pmath_string_t s)
Expand a string that contains boxes to a list of Strings and Boxes.

- PMATH_API `pmath_t pmath_parse_string (pmath_string_t code)`
Parse a string to an expression.
- PMATH_API `pmath_t pmath_parse_string_args (const char *code, const char *format,...)`
Parse a string with additional arguments to an expression.

8.16.1 Detailed Description

The string class.

Because `pmath_string_t` is derived from `pmath_t`, you can use strings wherever a `pmath_t` is accepted. E.g. you compare two strings with `pmath_compare()` or `pmath_equals()`.

The `pmath_type_t` of strings is `PMATH_TYPE_STRING`.

See also:

[Objects - the Base of pMath](#)

The documentation for this class was generated from the following files:

- `pmath-core/strings.h`
- `pmath-language/scanner.h`

8.17 `pmath_symbol_t` Class Reference

The Symbol class.

Inherits `pmath_t`.

Public Member Functions

- PMATH_API `pmath_symbol_t pmath_symbol_get (pmath_string_t name, pmath_bool_t create)`
Get a symbol by its fully qualified name.
- PMATH_API `pmath_symbol_t pmath_symbol_create_temporary (pmath_string_t name, pmath_bool_t unique)`
Create a new temporary symbol.
- PMATH_API `pmath_symbol_t pmath_symbol_find (pmath_string_t name, pmath_bool_t create)`
Find a symbol in the current namespace search path.
- PMATH_API `pmath_string_t pmath_symbol_name (pmath_symbol_t symbol)`
Get a symbol's name.
- PMATH_API `pmath_symbol_attributes_t pmath_symbol_get_attributes (pmath_symbol_t symbol)`
Get a symbol's attributes.

- PMATH_API void `pmath_symbol_set_attributes` (`pmath_symbol_t` symbol, `pmath_symbol_attributes_t` attr)
Set a symbol's attributes.
- PMATH_API `pmath_t` `pmath_symbol_get_value` (`pmath_symbol_t` symbol)
Get a symbol's value.
- PMATH_API void `pmath_symbol_set_value` (`pmath_symbol_t` symbol, `pmath_t` value)
Set a symbol's value.
- PMATH_API void `pmath_symbol_synchronized` (`pmath_symbol_t` symbol, `pmath_callback_t` callback, void *data)
Execute a function synchronized to a symbol.
- PMATH_API void `pmath_symbol_update` (`pmath_symbol_t` symbol)
Update a symbol manually.

Related Functions

(Note that these are not member functions.)

- PMATH_API void `pmath_collect_temporary_symbols` (void)
Collect unused symbols with the Temporary attribute.

8.17.1 Detailed Description

The Symbol class.

The pMath language knows symbols as 'named entities' that can hold any pMath object as a value and have some attributes. Those symbols are objects themselves. A symbol name consists of alphanumerical characters (a-z,A-Z,0-9) and apostrophes to separate namespaces. All standard symbols are in the "System" namespace (e.g. System'print). All user defined symbols go to "Global". Every other module has its own namespace.

Because `pmath_symbol_t` is derived from `pmath_t`, you can use strings wherever a `pmath_t` is accepted. E.g. you compare two symbols with `pmath_compare()` or `pmath_equals()`.

The `pmath_type_t` of symbols is PMATH_TYPE_SYMBOL.

See also:

[Objects - the Base of pMath](#)

8.17.2 Friends And Related Function Documentation

8.17.2.1 PMATH_API void `pmath_collect_temporary_symbols` (void) [related]

Collect unused symbols with the Temporary attribute.

This function is called periodically by the garbage collector.

See also:

[pmath_symbol_attributes_t](#)

The documentation for this class was generated from the following files:

- pmath-core/symbols.h
- pmath-util/concurrency/threadpool.h

8.18 pmath_t Class Reference

The basic type of all pMath objects.

Inherited by [pmath_custom_t](#), [pmath_expr_t](#), [pmath_number_t](#), [pmath_string_t](#), and [pmath_symbol_t](#).

Public Member Functions

- PMATH_API [pmath_t](#) [pmath_ref](#)([pmath_t](#) obj)
Increments the reference counter of an object and returns it.
- PMATH_API void [pmath_unref](#)([pmath_t](#) obj)
Decrements the reference counter of an object and frees its memory if the reference counter becomes 0.
- PMATH_API [pmath_bool_t](#) [pmath_instance_of](#)([pmath_t](#) obj, [pmath_type_t](#) type)
Determine whether an object has a specific type.
- PMATH_IS_MAGIC(obj)
Fast test, whether an object is a 'magic value'.
- PMATH_API unsigned int [pmath_hash](#) ([pmath_t](#) obj)
Calculates an object's hash value.
- PMATH_API [pmath_bool_t](#) [pmath_equals](#) ([pmath_t](#) objA, [pmath_t](#) objB)
Compares two objects for identity.
- PMATH_API int [pmath_compare](#) ([pmath_t](#) objA, [pmath_t](#) objB)
Compares two objects syntactically.
- PMATH_API void [pmath_write](#) ([pmath_t](#) obj, [pmath_write_options_t](#) options, [pmath_write_func_t](#) write, void *user)
Write an object to a stream.
- PMATH_API [pmath_bool_t](#) [pmath_is_evaluated](#) ([pmath_t](#) obj)
Test whether an object is already evaluated.

Related Functions

(Note that these are not member functions.)

- PMATH_API `pmath_t pmath_evaluate (pmath_t obj)`
Evaluate an object.
- PMATH_API `pmath_t pmath_build_value_v (const char *format, va_list args)`
Generate a List of objects with a format string.
- PMATH_API `pmath_t pmath_build_value (const char *format,...)`
Generate a List of objects with a format string.

8.18.1 Detailed Description

The basic type of all pMath objects.

Note that this is not necessarily a pointer to some accessible piece of memory. Use `pmath_instance_of()` to determine whether an object is of a specific type or set of types.

You must free unused objects with `pmath_unref()`.

8.18.2 Friends And Related Function Documentation

8.18.2.1 PMATH_API `pmath_t pmath_evaluate (pmath_t obj)` [related]

Evaluate an object.

Parameters:

obj Any pMath object. It will be freed. Do not use it afterwards.

Returns:

A new object produced by pMath's and user defined evaluation rules.

The documentation for this class was generated from the following files:

- `pmath-core/objects.h`
- `pmath-core/objects-inline.h`
- `pmath-util/evaluation.h`
- `pmath-util/helpers.h`

8.19 `pmath_text_file_api_t` Class Reference

Access functions for text files.

Data Fields

- [size_t struct_size](#)
The structure size. Always initialize this with sizeof (pmath_binary_file_api_t).
- [pmath_files_status_t\(* status_function\)](#)(void *extra)
A function to get the current file status This can be NULL if read_function is also NULL.
- [pmath_string_t\(* readln_function\)](#)(void *extra)
An optional callback function for reading one line.
- [pmath_bool_t\(* write_function\)](#)(void *extra, const uint16_t *str, int len)
An optional callback function for writing one line.
- [void\(* flush_function\)](#)(void *extra)
An optional callback function for flushing an output buffer.

8.19.1 Detailed Description

Access functions for text files.

See also:

[pmath_file_create_text](#)

The documentation for this class was generated from the following file:

- pmath-util/files.h

8.20 pmath_thread_t Class Reference

The Representation of a thread.

Related Functions

(Note that these are not member functions.)

- PMATH_API [pmath_messages_t pmath_thread_fork_daemon](#) ([pmath_callback_t](#) callback, [pmath_callback_t](#) kill, void *data)
Create a new deamon thread.
- PMATH_API [pmath_thread_t pmath_thread_get_current](#) (void)
Get the current pMath thread.
- PMATH_API [pmath_thread_t pmath_thread_get_parent](#) ([pmath_thread_t](#) thread)
Get a thread's direct parent.
- PMATH_API [pmath_bool_t pmath_thread_is_parent](#) ([pmath_thread_t](#) parent, [pmath_thread_t](#) child)

Queries whether a thread is one of the parents of another.

- PMATH_API `pmath_bool_t pmath_thread_aborting (pmath_thread_t thread)`

Queries whether pMath was requested to abort the evaluation of a specific thread or its parents.

8.20.1 Detailed Description

The Representation of a thread.

Every operating system thread that runs pMath functions has its own `pmath_thread_t` after it successfully initialized with `pmath_init()`.

Todo

Implement `pmath_run_parallel(number_of_parallel_threads, callback)`.

8.20.2 Friends And Related Function Documentation

8.20.2.1 PMATH_API `pmath_messages_t pmath_thread_fork_daemon (pmath_callback_t callback, pmath_callback_t kill, void * data)` [related]

Create a new daemon thread.

Parameters:

callback The thread function.

kill An optional function to inform the thread that it will be killed.

data A pointer to be passed to `callback()` and `kill()`

Returns:

A reference to the new thread's message queue or NULL on error. You have to destroy the result.

pMath will automatically kill any daemon thread when there are no other threads remaining (normally, when `pmath_done()` is called from `main()`). Killing daemons works as follows:

```
for each daemon thread t:
    call t->kill() if the method exists
    throw PMATH_ABORT_EXCEPTION in t

for each daemon thread t:
    wait for t to finish (to return from t->callback)
```

`pmath_init()` will be called automatically before `callback()` and `pmath_done()` after `callback` returns. So the pMath thread (`pmath_get_current()`) will be already initialized and you must not call these two functions in the *callback* routine.

You can use the *kill* function to set your own abort-please-flags if nessecary.

The documentation for this class was generated from the following files:

- `pmath-util/concurrency/threads.h`
- `pmath-util/concurrency/threadpool.h`

8.21 `pmath_threadlock_t` Class Reference

A reentrant lock for threads.

Related Functions

(Note that these are not member functions.)

- `PMATH_API void pmath_thread_call_locked (pmath_threadlock_t *threadlock_ptr, pmath_callback_t callback, void *data)`

Execute a function synchronized with a threadlock.

8.21.1 Detailed Description

A reentrant lock for threads.

A thread lock is like a thread lock, but it does not block child threads of the currently holding thread.

The documentation for this class was generated from the following file:

- `pmath-util/concurrency/threadlocks.h`

8.22 `pmath::String` Class Reference

A wrapper for `pmath_string_t`.

Inherits `pmath::Expr`.

Public Member Functions

- `String (pmath_string_t _str=0) throw ()`
Construct from a `pmath_string_t`, stealing the reference.
- `String (const char *latin1, int len=-1) throw ()`
Construct from Latin-1 encoded C string.
- `String part (int start, int length) const throw ()`
Get string part.
- `bool equals (const char *latin1) const throw ()`
Check for equality with a C string.
- `bool starts_with (const String &s) const throw ()`
Check for prefix equality.
- `bool starts_with (const char *s, int len=-1) const throw ()`
Check for prefix equality with a C string (Latin-1).
- `bool starts_with (const uint16_t *s, int len=-1) const throw ()`

Check for prefix equality with a UCS-2/UTF-16 string.

- void [insert](#) (int pos, const [String](#) &other) throw ()
Insert a substring. Changes the object itself.
- void [insert](#) (int pos, const char *latin1, int len=-1) throw ()
Insert a substring. Changes the object itself.
- void [insert](#) (int pos, const uint16_t *ucs2, int len=-1) throw ()
Insert a substring. Changes the object itself.
- void [remove](#) (int start, int length) throw ()
Remove a substring. Changes the object itself.
- int [length](#) () const throw ()
Get the string length.
- const uint16_t * [buffer](#) () const throw ()
Get the UCS-2/UTF-16 const string buffer. This is not zero-terminated.
- uint16_t [operator\[\]](#) (int i) const throw ()
Get a single character or U+0000 on error.
- const [pmath_string_t](#) [get_as_string](#) () const throw ()
Get the underlying [pmath_string_t](#). It remains owned by this object.

Static Public Member Functions

- static [String FromUcs2](#) (const uint16_t *ucs2, int len=-1) throw ()
Construct from UCS-2/UTF-16 encoded string.
- static [String FromChar](#) (unsigned int unicode) throw ()
Construct from a unicode character.
- static [String FromUtf8](#) (const char *utf8, int len=-1) throw ()
Construct from UTF-8 encoded C string.

8.22.1 Detailed Description

A wrapper for [pmath_string_t](#).

This class provides some string utility functions in addition to [Expr](#).

The documentation for this class was generated from the following file:

- [pmath-cpp.h](#)
